From the dawn of civilization man has employed the rotating earth to divide the steady flow of time into units which he calls "solar days"; and these were early refined by the astronomer into mean solar days. Natural units of length, such as the foot, have doubtless been in use ever since man began to walk in an upright position. Thus early in human history these three measurements of mass, time, and length were considered to be fundamental. Corresponding standards of mass, length and volume were preserved in the temples and other public buildings of antiquity for the purpose of stabilizing the measures employed in trade. Yet among these standards—these bases of comparison—there existed throughout the nations of Europe up to the beginning of the 19th century the utmost diversity of size and name.

Algebra, geometry and calculus are all independent of scale. These call for no particular set of units. The first demand for uniformity came neither from the mathematicians nor from the natural philosophers but mainly from the tradesmen in neighbouring provinces. Yet in the 17th century when the great national academies sprang up and their members were exchanging opinions through a voluminous correspondence, there frequently occurred a diversity of results which could be harmonized only through a comparison of units. Among English-speaking nations the use of the foot, pound and second for commercial purposes has been universal. On the continent of Europe, however, the unit of time has been the only common standard. It was, indeed, only in the last decade of the 18th century that any serious action was taken to ease trade and facilitate exchanges by coming to an international agreement concerning units.

Invention of the Metric System.—The initiative was taken by the National Assembly of France in 1791 when it appointed a commission of 12 outstanding men of science to revise the French system of weights and measures. These men made this revision in a manner which was at once so simple, so clear and so natural that it later won acceptance by many other nations. The chief concern of this commission was of course the two units of length and mass, since the third fundamental unit, time, had been provided for by the astronomers who, in their observations and tables, were using 1/86,400 of a mean solar day as the second of time.

For the unit of length the National Assembly adopted a decimal fraction of the earth's meridian. Eight years were then employed by the geodesists in an accurate determination of the arc from Dunkirk to Barcelona. On Dec. 10, 1799, the French Legislative Assembly voted to define their standard of length—to be called the metre—as the 10^{-7} part of the earth's quadrant.

On the same day the mass of a cubic decimetre of water, at its

maximum density, was chosen as the standard of mass and was named the kilogram.

One might expect that such a clear and simple system would obtain ready adoption among the nations of western Europe and America. France made the use of these units compulsory, beginning with the year 1801; but the conservatism of the merchants, who had been selling cloth by the ell, and of the farmers, who sold meat and vegetables by the livre, was too strong to be affected by the law of 1801. The result was that in 1837 a more stringent law was passed penalizing the use of any units except the metre and the kilogram after Jan. 1, 1840.

Up to this time (1840) only two nations besides France had adopted the metric system. These were Greece and the Netherlands. England authorized its use in 1864, the United States in 1866 and Germany in 1868. Since then the metric system has been legalized by all the leading nations of the world. In Europe and South America its use is well-nigh exclusive.

Creation of the International Bureau of Weights and Measures.—In 1875 each of 20 different nations accepted the invitation of France to send two delegates to a *conférence diplomatique du mètre* at Paris. A proposal to establish an international standardizing bureau had been discussed by an earlier international convention held in 1872; and this conference of 1872, before its adjournment, had practically created such a bureau, had outlined its duties as the custody and comparison of standards and had even made financial provision for the work. All of these plans were later ratified by the national governments concerned. The International Bureau of Weights and Measures was, therefore, by 1875, a *fait accompli*; and has ever since remained, in its pavilion near Sèvres, not only a safe depository for the international standards but also a laboratory for the certification of copies and related problems. As early as 1867 metrologists had already begun to suspect that the original standard metre, known as the *mètre des archives*, might not be very permanent since it was an end measure and therefore subject to slight abrasion in use. The choice of the proper material and the preparation from it of a new bar upon which the metre could be duplicated in line measure thus became one of the first problems which fell to the international committee.

Abandonment of Natural for Arbitrary Standards.—When, by the autumn of 1889, this committee had completed the new platinum-iridium bar for the metre and a platinum-iridium cylinder for the kilogram, it deposited these two prototypes in the underground vault at the International bureau and immediately proceeded to change the definitions of these two units from natural to purely arbitrary quantities. Without any reference to a quadrant of the earth's meridian, the following resolution was passed concerning the polished Pt-Ir bar, upon which two fine rulings had been selected as marking the standard of length: "This prototype, at the temperature of melting ice, shall henceforth represent the metric unit of length." Similar action, without any reference to a cubic decimetre of water, was taken with regard to the new kilogram: "This prototype will henceforth be considered to be the unit of mass." The fact that standards of length and weight can be copied with much greater accuracy than they can be determined afresh from some natural unit thus decided the question forever in favour of the arbitrary standard.

When the kilogram was first defined as the mass of a cubic decimetre of water at the temperature of its maximum density, the unit of density was taken to be that of water at this same temperature. The litre was defined as the volume of a cubic decimetre; and was therefore taken to be identical with the volume of a kilogram of water.

During the first half of the 19th century, however, precision of measurements increased to such an extent that a distinct difference was detected between 1,000 cubic centimetres and the volume of a kilogram of water.

Accordingly in 1901, the following definition was formulated:

The unit of volume, for determinations of higher precision, is the volume occupied by the mass of one kilogram of pure water at its maximum density and under normal atmospheric pressure; this volume is called the *litre*.

The relation between the litre and the cubic decimetre now became a matter of experimental determination. The accepted value is

$$1 \text{ litre} = 1000.028 \pm 0.002 \text{ cm}^3.$$

The practice recommended by the bureau of standards and the National Physical laboratory is to graduate standard volumetric glassware in millilitres—marked "ml." instead of "cc." Where the volume is derived from geometrical dimensions, the appropriate unit is "cm³."

Introduction of Electrical Standards.—In the early years of the 19th century there had grown up a new science of electricity and magnetism, whose phenomena exhibited themselves mainly by mechanical effects. In the industrial field units of power, work and energy had been introduced in a somewhat haphazard manner. Superposed upon these were certain electrical measurements. The earliest introduction of order into this chaos of units came in the three following steps, taken by men who had the vision to see that magnetic and electrical effects must be measured in terms of mechanical quantities.

1. The first advance was made by the astronomer, K. F. Gauss, in 1833, when he published from Göttingen his great paper "On the Intensity of the Earth's Magnetic Field, Expressed in Absolute Measure." Here, by two simple quantitative experiments, he measured the strength of the earth's magnetic field, H , in terms of length, mass and time, much after the manner of using the pendulum to measure the earth's gravitational field.

2. The second step was to determine in absolute measure, *i.e.*, in fundamental units, the force which produces electric currents, the force which Volta (1745–1827) called "electromotive" and which is generally denoted by e.m.f. This step was accomplished by F. E. Neumann (1798–1895) in 1845 when he formulated Faraday's great discovery of 1831 in the following expression, $E = -dN/dt$, where E is the e.m.f. generated in a closed circuit, through which the number of magnetic lines of force is changing at the rate of dN/dt . Electromotive force is thus reduced to mechanical measure.

3. The third step was taken in 1851 by W. E. Weber (1804–91), who used Neumann's idea and Pouillet's tangent galvanometer to measure an induced current in absolute units. Having thus measured both e.m.f. and current, for one and the same circuit, he was able, by use of Ohm's law, to compute the electrical resistance of the circuit in absolute measure. Simpler and more accurate methods have since been devised by Lorenz, Rosa and others (*see bibliography*).

As early as 1851, Helmholtz and Kelvin had introduced the idea of electrical work and had explained the meaning of the following equation:

$$\text{work} = \text{power} \times \text{time} = Eit = i^2 Rt,$$

which is the connecting link between all physical measurements. Thus by the middle of the 19th century the quantities in Table I had already been defined in terms of electromagnetic units.

TABLE I.—The Electromagnetic Sequence; Middle of 19th Century

Defining equation	Quantity defined
1. $H = \frac{2\pi}{T} \sqrt{\frac{2I}{r^3 \tan \theta}}$	Magnetic field strength
2. $M = F/H$	Magnetic pole strength
3. $i = \frac{rH \tan \theta}{2\pi}$	Electric current by tangent galv
4. $E = W/it$	Electromotive force in terms of work
5. $R = E/i$	Electric resistance
6. $Q = it$	Electric quantity
7. $C = Q/E$	Electric capacity

Besides these seven quantities, coefficients of self- and mutual-induction had been defined; and their values, in certain cases, had been computed from the mechanical dimensions of the system. Yet great confusion existed because various observers, using the same fundamental quantities, had employed different units. All was arbitrary. Nothing was coherent save the underlying principles of physics. Computation was tedious because of needless conversion factors.

Unit of Resistance.—At this stage the problem was taken up by the British Association for the Advancement of Science when, at the Manchester meeting in 1861, it acted upon the advice of two eminent telegraph engineers (Latimer Clark and Charles Bright) and appointed a committee on electrical standards of resistance. In a series of six annual reports, ending in 1869, this committee had established the essential theory of units (*i.e.*, the principles which must control any consistent and useful system), had recommended as fundamental units the metre, gram and second, and had prepared a wire standard (known as the "B.A. unit") which was as nearly as then possible equal to 10^7 m.g.s. units of resistance.

A second B.A. committee, appointed in 1872, recommended, in its annual report, a change to the centimetre-gram-second system and also the adoption of the name ohm for a unit of resistance which should be, as nearly as realizable, equal to 10^8 c.g.s. absolute units. Both of these recommendations were adopted by the first International Congress of Electricians meeting in Paris in 1881. One important consideration in fixing upon this size for the ohm was that it thus closely approximated the "Siemen's unit," which is a uniform thread of mercury having a length of one metre and a cross-sectional area of one square millimetre. At this period the Siemens unit was widely used over Germany.

Unit of Electromotive Force.—Beginning with the year of its invention, 1800, a single voltaic cell has been steadily used as the unit of e.m.f. First came the Daniell cell; then the Bunsen; later the Clark; but now the cadmium cell of Edward Weston is universally employed. Compared with any one of these cells, the c.g.s. unit of e.m.f., defined by Neumann's formula, is almost infinitesimal. Accordingly a practical unit of 10^8 c.g.s. units, bearing the name volt, was approved both by the British association and by the International Congress of Electricians in 1881.

The Absolute Practical System of Units.—In this terminology the word absolute signifies that the unit (volt, ohm, etc.) is defined in terms of the c.g.s. mechanical unit by a numerically simple relationship; and the word practical signifies that the magnitude of the unit, except for the unit of capacitance, is of a size convenient to use in practical engineering work. Besides the ohm and volt, three other practical units were established, at this same congress, by the following resolutions:

That the current produced by a volt in the ohm be called an *ampere*.
That the quantity of electricity produced by a current of one *ampere* in one second be called a *coulomb*.

That the unit of capacity be called a *farad*, which is defined by the condition that a *coulomb* in a *farad* raises the potential one volt.

In view of this action, it is evident that the practical system was, in its essential features, complete when the congress of 1881 adjourned. From this time on the measuring instruments of electrical engineers were graduated in practical units; *i.e.*, in units of the same order of magnitude as those already employed in laboratories and shops. Alongside these two electromagnetic systems there grew up, in response to electrical theory, a third system known as the electrostatic c.g.s. units. They are of minor importance (*see bibliography*).

The second International Congress of Electricians, meeting at Paris in 1889, defined three more practical units as follows:

The *joule*, the practical unit of energy is equal to 10^7 c.g.s. units. It is equal to the energy disengaged as heat in one second by a current of one *ampere* flowing through a resistance of one *ohm*.

The practical unit of power is the *watt*. The *watt* is equal to 10^7 c.g.s. units and is the power of one *joule* per second.

The practical unit of self-inductance is the *quadrant* which is equal to 10^9 c.g.s. units.

With these eight practical units already agreed upon, the subject came before the fourth International congress held at Chicago in 1893. Here the name of the unit of inductance was changed from quadrant to henry, and the international system of units was set up.

The International System of Electrical Units.—Since the practical units were defined in terms of the c.g.s. electromagnetic units, there arose a need for a system of units to be used in electrical measurements. Such a system was called the International

System of Units; its units were made as close as possible to the corresponding units in the absolute practical system. At the Chicago congress the international ohm was defined as "the resistance of a column of mercury of uniform cross-section, having a length of 106,300 cm and a mass of 14.4521 gm when the temperature is 0° C." The international ohm thus defined represented the best experimental result of that time (1893) in realizing a resistance of 10^9 c.g.s. units or 1 absolute practical ohm. It was larger than the B.A. ohm in the ratio of 1 to 0.9866. The congress at Chicago also defined the international ampere as that "unvarying current, which, when passed through a solution of nitrate of silver in water in accordance with standard specifications, deposits silver at the rate of 0.001118 grams per second." This was made as close as possible to the absolute practical ampere which is 0.1 of the c.g.s. unit of current.

A third unit, the international volt, was so defined that a Clark cell at 15° C. had an e.m.f. of 1.434 international volts. This international volt was as close as possible to 10^8 c.g.s. units of potential difference, that is, an absolute practical volt.

As more and more units and standards were established a need was felt for standardizing laboratories in the various industrialized nations. Thus were established the German Physikalisch-Technische Reichsanstalt in 1887, the English National Physical laboratory in 1899 and the United States national bureau of standards in 1901. These laboratories carried on very careful measurements on the various standards.

From their work it became apparent that the recommendations at the Chicago congress were not consistent with the definition that the international volt is "the electromotive force that, steadily applied to a conductor whose resistance is 1 international ohm, will produce a current of 1 international ampere." This situation was corrected at the London International conference in 1908 by keeping the international ohm and ampere as primary units and letting the international volt be a derived unit. The conference also agreed that "as heretofore the magnitudes of the fundamental electric units shall be determined on the electro-magnetic system of measurement with reference to the centimeter as the unit of length, the gramme as the unit of mass and the second as the unit of time." The various national standardizing laboratories were conducting experiments in which the electrical units, ampere, ohm, etc., were measured directly in terms of forces. Thus in 1935 the International Committee on Weights and Measures announced that after Jan. 1, 1940, the absolute practical units would be based directly upon the electromagnetic units. This decision was held in abeyance during World War II and in 1946 the same committee set Jan. 1, 1948, as the date for the change. Thus on the latter date the international units became obsolete and the absolute practical units, ampere, ohm, etc., were measured in terms of forces and other mechanical units. Much of this difficult and important work was done at the bureau of standards. From these experimental results the International committee fixed the following quantities as of Jan. 1, 1948:

1 mean international ohm	= 1.00049 absolute ohms
1 mean international volt	= 1.00034 absolute volts
1 mean international ampere	= 0.99985 absolute amperes

Thus all electrical measurements became based on the absolute practical system of units. The recommendations of this committee included the use of the metre, kilogram, second as fundamental units in place of the centimetre, gram, second. Thus the powers of ten, which were used with the c.g.s. electromagnetic units, could be eliminated. This fact was first pointed out by G. Giorgi of Rome in 1901.

The m.k.s. or Giorgi System of Units.—At the sixth International congress held in St. Louis, Mo., in 1904 Giorgi showed that by taking the metre, kilogram, second and ohm as the four fundamental and arbitrary units the system of absolute practical units would remain unchanged. The m.k.s. or metre-kilogram-second system of units forms a complete and logical system for the mechanical units. If the electrical practical units are to be included then a fourth unit from among the various electrical ones must be added. Giorgi used the ohm though any one from among the following practical units, ampere, ohm, volt, henry, farad,

coulomb or weber, may equally well serve as the fourth unit since all these quantities are interrelated by electromagnetic theory. The International Committee on Weights and Measures adopted the following resolutions in 1946 from which we see that the ampere was selected as the fourth unit:

A. Definition of Mechanical Units in the M.K.S. system.

- I. The Newton (unit of force).—The newton is the force which gives to a mass of 1 kilogram an acceleration of 1 meter per second per second.
- II. The Joule (unit of energy or work).—The joule is the work done when the point of application of the newton is displaced a distance of 1 meter in the direction of the force.
- III. The Watt (unit of power).—The watt is the power which gives rise to the production of energy at the rate of 1 joule per second.
- B. Definition of the Electrical Units.
- IV. The Ampere (unit of electric current).—The ampere is the constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular sections, and placed 1 meter apart in a vacuum, will produce between these conductors a force equal to 2×10^{-7} newtons per meter of length.
- V. The volt (unit of potential difference and electromotive force).—The volt is the difference of electric potential between two points of a conducting wire carrying a constant current of 1 ampere, when the power dissipated between these points is equal to 1 watt.
- VI. The ohm (unit of electric resistance).—The ohm is the electric resistance between two points of a conductor when a constant difference of potential of 1 volt, applied between these two points, produces in this conductor a current of 1 ampere, this conductor not being the seat of any electromotive force.
- VII. The Coulomb (unit of quantity of electricity).—The coulomb is the quantity of electricity transported in 1 second by a current of 1 ampere.
- VIII. The Farad (unit of electric capacitance).—The farad is the capacitance of a capacitor between the plates of which there appears a difference of potential of 1 volt when it is charged by a quantity of electricity equal to 1 coulomb.
- IX. The Henry (unit of electric inductance).—The henry is the inductance of a closed circuit in which an electromotive force of 1 volt is produced when the electric current in the circuit varies uniformly at a rate of 1 ampere per second.
- X. The Weber (unit of magnetic flux).—The weber is the magnetic flux which, linking a circuit of 1 turn, produces in it an electromotive force of 1 volt as it is reduced at a uniform rate in one second.

The definitions given above are intended to fix the magnitude of the units and are not necessarily the methods followed for their practical determination. For example, the definition of the ampere is only a particular case of the general formula expressing the forces between current-carrying conductors and is chosen for the simplicity of its verbal expression.

The experimental methods used in determining the absolute values of the electrical units can be found in the national bureau of standards circulars.

A question arising with every electrical system of units is whether the rationalized or the unrationalized form should be used. This question is concerned with the factor 2π or 4π in equations relating electrical quantities. In the rationalized system the factor 2π or 4π appears in the equations for those situations in which there is circular or spherical symmetry. In the unrationalized system the π factor does not appear in the equations for circular or spherical symmetry but does appear where there is no symmetry. It is not possible to get rid of π in one place without its appearing in another. The question was not new, for about 1890 Oliver Heaviside had written: "the unnatural suppression of 4π in the formulas of central force, where it has a right to be, drives it into the blood, there to multiply itself, and afterward break out all over the body of electromagnetic theory."

A system of units called the Heaviside-Lorentz system formed such a rationalized system and, though it was used in a number of theoretical treatises, did not come into general use because its units differ from those of the absolute practical system. In 1950 the International Electrotechnical commission voted the approval of the rationalized m.k.s.a. system. This action did not affect the absolute practical standards, ampere, volt, ohm, etc., but it did affect the values of the permeability and permittivity of free space.

In the rationalized system the equation for the force f per metre

length between two infinite parallel wires carrying circuits of I_1 , I_2 amperes and a distance of d metres apart in a vacuum is given by

$$f \left(\frac{\text{newton}}{\text{metre}} \right) = \frac{\mu_0 I_1 I_2}{2\pi d}$$

where μ_0 is the permeability of free space in the rationalized system and has a value of $4\pi \times 10^{-7}$ newtons/ampere². If I_1 and I_2 are each 1 ampere and d is 1 metre then the force per metre length is 2×10^{-7} newtons/metre as given in definition IV for the ampere.

In the unrationalized system the permeability of free space, μ'_0 is 10^{-7} newtons/ampere² and the force per unit length is given by

$$f \left(\frac{\text{newton}}{\text{metre}} \right) = \frac{2\mu'_0 I_1 I_2}{d}$$

This result of course agrees with definition IV. However there is circular symmetry in this problem and one might expect the factor π in the equation for the force as is the case in the rationalized system.

A similar situation exists in electrostatics for the permittivity ϵ_0 of free space. The capacitance C , in farads, of an electric condenser having plates of area A metre² separated by a uniform distance of d metres in a vacuum, is given in the rationalized system as

$$C = \frac{\epsilon_0 A}{d}$$

In the rationalized system ϵ_0 has the value of about 8.854×10^{-12} farads per metre. For the unrationalized system the permittivity ϵ'_0 of free space is about 1.1113×10^{-10} ($4\pi \times 8.854 \times 10^{-12}$) farads per metre and the capacitance C of this condenser is given by

$$C = \frac{\epsilon'_0 A}{4\pi d}$$

In this case there is no circular or spherical symmetry and the π factor does not appear in the equation written in the rationalized system.

These two constants, the permeability and permittivity of free space, are related by Maxwell's electromagnetic theory to the velocity of light c in free space in the following manner:

$$\mu_0 \epsilon_0 = \mu'_0 \epsilon'_0 = 1/c^2.$$

The value of c is about 3×10^8 metres per second.

The introduction of the m.s.k.a. rationalized system greatly simplified electromagnetic calculations. Previously there had been at least eight different systems of electrical units in fairly common use.

Dimensions of Units.—An expression containing the fundamental units which enter into the measure of any physical quantity, together with the powers to which they enter, is known as the "dimensions" of that quantity. Thus the dimensions of velocity are LT^{-1} ; those of acceleration LT^{-2} ; those of force MLT^{-2} . The importance of the subject lies mainly in the fact that, in an equation between physical quantities, each term, in both right-hand and left-hand members, must have the same dimensions. For fuller discussion, see DIMENSIONAL ANALYSIS.

A Short List of Important Miscellaneous Units

1. The unit of chemical atomic weight, 1 c.m.u. or one chemical mass unit, is one-sixteenth of the atomic weight of oxygen which is taken as exactly 16. It is known that oxygen consists of three isotopes, of mass numbers 16, 17 and 18 respectively of which the mass number 16 is 99.76% abundant. The physical mass unit, 1 m.u., is one-sixteenth of the isotope 16. The relationship between these units is:

$$1.00000 \text{ m.u.} = 0.99972 \text{ c.m.u.} = 1.65963 \times 10^{-27} \text{ kg.}$$

2. Because it is a much lighter task to compare the wave length of one ray of light with that of another ray than it is to compare either one with the length of a millimetre, astrophysicists agreed, at the meeting of the International Solar union

in 1907, that henceforth they would use, as a unit of wave length, $\frac{1}{100000000}$ of the wave length of the red cadmium ray. They also agreed to call it the angstrom and to denote it by the symbol Å. A. A. Michelson had already, in 1892, stabilized the standard metre at Sèvres by showing that its length is equal to 1,553,164.13 of these red cadmium wave lengths.

3. The charge of the electron—the smallest known natural unit of electricity and generally denoted by e —is $4.8025 \pm 0.0010 \times 10^{-10}$ absolute electrostatic c.g.s. units = 1.60203×10^{-19} coulombs.

4. Following are four units frequently used by astronomers:

The astronomical unit = distance from earth to sun,
= 149,501,201 kilometres
= 92,900,000 miles

The light second = 299,790 kilometres

The light-year = 9.4614×10^{15} metres, which is approximately 6,000,000,000,000 miles

The parsec = the distance at which the annual parallax of a star would be 1".
= 3.258 light-years = 3.0838×10^{16} metres

5. Three units of heat are in frequent use, viz.: the gram-calorie, which is the quantity of heat required to raise the temperature of one gram of water through 1°C .; the kilogram-calorie = 1,000 gram-calories; the British thermal unit—B.Th.U.—which is the quantity of heat required to raise the temperature of one pound of water through 1°F .

6. The unit of intensity of light is the candle, which is one-sixtieth of the intensity of one square centimetre of a perfect radiator, known as a "black body," when operated at the temperature of freezing platinum.

The unit of light flux is the lumen, which is the flux in a unit of solid angle from a source of which the intensity is one candle. The total radiation from one candle is, therefore, 4π lumens.

7. The international radium standard is kept at the International Bureau of Weights and Measures at Sèvres. It consists of 21.09 g. of anhydrous RaCl_2 , prepared by Mme. Marie Curie. Other quantities of radium are measured by comparing their X radiation with that of the standard. In this manner secondary radium standards have been made and distributed.

The amount of radon in equilibrium with one gram of radium element is called a curie. As radioactivity became more important the curie was used as a unit of disintegration rate and as such was not too satisfactory since it is difficult to measure accurately. Accordingly the International Radium Standard commission recommended that the curie be defined as 3.7×10^{10} radioactive disintegrations per second.

A newer and more convenient unit for the rate of disintegration of a radioactive substance was recommended by the national bureau of standards. This is called the rutherford (rd) where 1 rd is the amount of radioactive substance which undergoes 10^6 disintegrations per second.

For personnel protection a unit of X or gamma radiation called the roentgen, r, is used. This is defined in the following manner: 1 r unit is "that quantity of X or gamma radiation such that the associated corpuscular emission per 0.001293 gms of air produces, in air, ions carrying 1 esu (about $\frac{1}{3} \times 10^{-9}$ coulombs) of quantity of electricity of either sign."

8. The barye (= dyne/cm.²) is the c.g.s. unit of pressure. The bar (= 10^6 dynes/cm.² = 1.013 kg./cm.^2 = 0.987 atm.) is the international unit of pressure.

9. X-unit (= 10^{-11} cm. = 10^{-8} Å) is used in X-ray work. (See also MEASURES AND WEIGHTS.)

PHYSICS (ARTICLES ON). The astonishing advances which the science of physics has made since the 11th edition of the *Encyclopædia Britannica* was prepared early in the 20th century is evidenced by the fact that the 11th edition contains nothing on relativity, on atomic structure or on the quantum theory, three questions which dominate modern physics and influence every branch.

The articles SCIENCE and PHYSICS: GENERAL SURVEY give a general view of the scope of physics and its place among the sciences. The fundamental nature of space and time in the physical world and of gravitation, is discussed under RELATIVITY and SPACE-TIME, while the history of the growth and another aspect of the nature of the relativity problem is given under ETHER (IN PHYSICS). An account of experiments and observations which played a great part in preparing the way for relativity will be found under MICHELSON-MORLEY EXPERIMENT and ABERRATION OF LIGHT. Measurements of the VELOCITY OF LIGHT, the constancy of which is fundamental, are described under the article so entitled. The historical, experimental and theoretical aspects of the subject thus are all readily accessible.

The subject matter of physics can be broadly classed as matter and radiation. The physical nature of matter is expounded under KINETIC THEORY OF MATTER, which deals mainly with gases. Supplementary to this article is BROWNIAN MOVEMENT. The transition from gas to liquid is handled from the general theoretical point of view in the article LIQUEFACTION OF GASES, which also deals with technically important aspects of the subject. The modern view of solids comes under SOLID STATE PHYSICS. For the arrangement of atoms and molecules in crystalline solids the article CRYSTALLOGRAPHY should be consulted. Crystals have a regular ordered structure; in many ways the antithesis of the crystalline state is the colloidal state, dealt with under COLLOIDS. Important general properties of liquids have special articles, SURFACE TENSION and VISCOSITY, devoted to them. These articles, then, deal with the general properties of matter; the field of radiation is covered in RADIATION (RAYS), which deals broadly with the various kinds of waves comprised in the electromagnetic spectrum.

The peculiar task of physics in the present century has been to effect a synthesis of the properties of matter and radiation in terms of units of electric charge, of matter and of radiation. Modern atomic physics, which comprises this field, is well represented in the *Encyclopædia*. The unit of electricity is the ELECTRON, to which an article is devoted. A vast body of work that established and developed the electron theory is described under ELECTRICITY, CONDUCTION OF. The connecting link between matter and radiation is furnished by the nuclear theory of the atom, which asserts that an atom consists of a minute, positively charged massive nucleus, surrounded by groupings of electrons in motion. The general nuclear theory is explained under ATOM; the properties of the nucleus, and their profound consequences for physics and chemistry under NUCLEUS; NEUTRON; ISOTOPES.

RADIOACTIVITY, ARTIFICIAL and RADIOACTIVITY, NATURAL are articles of first importance for the understanding of modern physics. The theory of emission of light and X-rays by an atom, described under ATOM, is based upon the quantum theory, discussed in QUANTUM MECHANICS. COMPTON EFFECT; MOLECULAR SPECTRA; PHOTOELECTRICITY; RAMAN EFFECT; RESONANCE ENERGIES; SPECTROSCOPY; THERMIONICS; X-RAYS, NATURE of deal with the experimental and theoretical side of radiation phenomena which have a prominent place in atomic physics, while ACCELERATORS (PARTICLE) and WILSON CLOUD CHAMBER describe experimental methods that have had far-reaching results. See also ATOMIC ENERGY; PARTICLES, ELEMENTARY.

The general body of physics is dealt with under comprehensive articles devoted to the main conventional divisions—ELECTRICITY; ENERGY; HEAT; LIGHT; MAGNETISM; MECHANICS; SOUND; with important supplementary articles, among which may be mentioned: under heat, CALORIMETRY; THERMODYNAMICS; THERMOMETRY; under light, FLUORESCENCE and PHOSPHORESCENCE; OPTICS; SHADOW; SPECTROSCOPY; under electricity, ELECTRICITY, CONDUCTION OF.

Important instruments and their uses are described under: BALANCE;

BAROMETER; BINOCULAR INSTRUMENT; CHRONOGRAPHS; COMPASS; CONDENSER; ELECTRON MICROSCOPE; GYROSCOPE; HYDROMETER; INDUCTION COIL; INSTRUMENTS, ELECTRICAL MEASURING; INTERFEROMETER; MICROSCOPE; MICROSCOPY; MIRROR; SELENIUM CELLS; VACUUM.

Applied physics is another aspect of the subject which receives full representation. The meteorological side is represented by ELECTRICITY, ATMOSPHERIC; METEOROLOGY; the geophysical by EARTH CURRENTS; GEODESY; GEOPHYSICS; GRAVITATION; TERRESTRIAL MAGNETISM; and the astronomical by ASTROPHYSICS. Some of the chief heads under which the bearing of physics in everyday life and industry is described in detail are: ACOUSTICS OF BUILDINGS; AERODYNAMICS; CAMERA LUCIDA AND CAMERA OBSCURA; ELECTRIC LAMPS, MANUFACTURE OF; ELECTROMAGNET; GRAMOPHONE; LENS; PHOTOGRAPHY; PHOTOMETRY; RADAR; RADIOTELEGRAPHY; TELEGRAPH; TELEPHONE; TELEVISION; X-RAYS, NATURE OF: *Modern Industrial Applications.*

(E. N. D. C. A.; H. B. L.M.)

PHYSICS: GENERAL SURVEY. The study of nature, long called natural philosophy (from the Greek word *physikos*), the exact scope of which is not fixed nor easily delimited. From decade to decade in modern times, the principal effort in physics has changed as, on the one hand, fields of scientific knowledge were reduced to practice whereupon they were regarded as branches of engineering or applied physics; and, on the other hand, new fields were opened by fresh experimental or theoretical discoveries. Physics may be called a point of view about the natural world and a method of attack on its problems, a method based upon certain general principles and disciplined by the close interplay between experiment and theory. With a kind of confidence that the understanding of nature may be reduced to a few comprehensive principles, physicists seek for those central ideas by which great areas of common experience may be brought into order and coherence. To achieve their purpose, they proceed by use of mathematical and logical tools, and by experimentation.

Physics comprises especially the study of the structure of matter, the nature of radiation and its interactions with matter, and an attempt at a unified description of fields of force. It has been guided for the past century or more by three powerful conservation principles which appear to be valid in new areas of investigation and which in turn acquire increased stature as they meet the test in new experimental situations. The principle of conservation of linear and angular momentum, first applied to mechanics by the Englishman, Sir Isaac Newton (1642-1727), but later generalized to include the electrodynamic field, was the earliest of these. A principle of conservation of energy in mechanics was extended to other forms of energy, especially to heat, about the middle of the 19th century.

Since the enunciation of the mass-energy relation, $E=mc^2$, by Albert Einstein in 1905, the chemist's principle of the conservation of mass has been merged with the principle of conservation of energy into the more comprehensive principle of conservation of mass-energy. It appears that mass and energy have complementary properties: all transfers of energy from one body or system of bodies to another are accompanied by a corresponding transfer of mass rather than by annihilation of mass. All energy appears to exhibit inertia. In the equations of nuclear reactions, a term representing mass or energy changes is important, corresponding to the energy term in a complete chemical equation. The third principle is the conservation of electric charge, often an important guide, with the other two conservation principles, in the field of nuclear physics. In the balance of any nuclear equation, conservation of charge must be observed.

Insofar as these principles apply and are helpful in other sciences, physics may contribute to them and promote their development; and it has often happened that instruments designed for research in physics have found wide application elsewhere. The cathode ray tube, for example, was not invented to forward the art of television; rather, it was designed in prototype for the study of electrons. This article will deal more with basic ideas than with applications of physics. Because of the rapid growth of all science, it has been convenient to set up somewhat arbitrary and often indefinite boundaries between the various fields. In particular, physics was once regarded as dealing with inanimate objects; it has been said, somewhat jocularly, that if there was any life in the subject, it could not be physics. Biology deals with the great area of life sciences, but a growing field of biophysics

suggests the temporary nature of such a boundary. Astronomy underwent radical changes after 1850 as it became to an increasing extent astrophysics. To the telescope, spectroscope, spectroheliograph and kindred instruments was added the radiotelescope; and there has been a busy two-way traffic of ideas between atomic and nuclear physics and astronomy. Geology has become in part geophysics. Meteorology is largely a study of the physics of the air. At no time has it ever been possible to draw a sharp line between chemistry and physics, as each has contributed continuously to the other. Few ideas are important in one field that do not have wide applicability in the other. This relationship is obviously apparent in the rapid development of such fields as radioactivity, nuclear energy and isotopes, in which progress has been shared repeatedly by those who called themselves either physicists or chemists.

For convenience, the field of physics is often broken into several related subfields, all of which are viewed through the same general conservation principles, although each field may have in addition its own distinctive ideas and generalizations. These fields are (somewhat in historical order of development) mechanics, heat, sound, light, magnetism, electricity, and atomic and nuclear structure. In addition, there have developed certain broad mathematical theories by which fields of knowledge are for the time systematized. (See *Theory* below.) A partial list of these subfields, starting with *Philosophiæ Naturalis Principia Mathematica*, Newton's great 1686-87 treatise on mathematical principles of natural philosophy, includes electrodynamics, kinetic theory, thermodynamics, statistical mechanics, quantum mechanics and relativity. In this article, only brief mention will be made of some of these fields; but the reader may also consult PHYSICS (ARTICLES ON) for the titles of the separate articles dealing with the various subfields.

History.—Throughout the centuries men gained a certain practical working knowledge of nature but it was seldom systematized or elevated to the level of general principles. Early philosophical ideas about nature were often void of adequate basis in observation and many were barren of consequences. For example, the Greeks Democritus and Leucippus (both 5th century B.C.) are referred to as early atomists, but it is not evident that their ideas bore fruit. The development of a productive atomic theory had to await the experimental researches of the 19th century. For 24 centuries, little came from Thales' early reports of static electricity and magnetism. The fact that, before 400 B.C., Philolaus reduced the earth to the status of a planet seems to have had little influence on men's thinking for the next 1,800 years. Archimedes (c. 287-212 B.C.) was one of the more successful mathematicians and experimentalists, whose law of the lever and principle of buoyancy laid the foundation of a science of mechanics. Throughout the first 15 centuries of the Christian era, little concerted effort was expended on understanding nature, although it would be uncharitable to discount the value of the accumulated ideas, mathematical and astronomical, which were available when the renaissance of learning occurred.

The birth of physics may be said to have resulted from a new attitude typified by precise, quantitative observation and controlled experimentation, coupled with mathematical reasoning. With control of experiments and success of logical predictions derived from them, there came a sense of man's growing power to bend nature to his needs. The physical world was increasingly regarded as understandable and predictable, rather than capricious. Two of the larger developments will be sketched briefly as examples of how physics proceeds, not at a uniform rate unerring in direction, but by large and small steps and by the interplay of observation and theory. The first of these, in the very large, concerns the solution of the solar system; the second, in the very small, the growth and consequences of the electrical nature of matter.

Solar System.—Despite a few early claims for the earth's sphericity and its planetary status, a geocentric view of the solar system prevailed for many centuries. Copernicus demonstrated in 1543 that a great simplification in the observed motions of the planets could be made by assuming the earth also to be a planet revolving around the sun. His hypothesis reopened the question of the

earth's position in the universe, but it remained only hypothesis for more than a hundred years before other significant steps were taken. The Danish astronomer Tycho Brahe (1546–1601) contributed a vast quantity of precise observational material on the positions of the planets. His disciple, the German astronomer Johann Kepler (1571–1630), reduced this data to order and extracted from it three empirical laws of planetary motion. These conclusions were that the planets (1) move in ellipses about the sun, with the sun at one focus; (2) sweep out, by their radius vectors, equal areas in equal times; (3) have periods of revolution about the sun such that the squares of these periods are proportional to the cubes of the respective major axes of their elliptical orbits. Kepler could not guess the full meaning of his findings because of the prevailing lack of knowledge of mechanics and of any comprehensive system of understanding.

In Italy Galileo (1564–1642) contributed two important advances, first by the invention of a telescope which revealed the moons of Jupiter like a miniature Copernican system and showed the phases of the planet Venus as it moved about the sun; second, by laying a firmer foundation in mechanics as a forerunner of the more complete work of Newton. Newton grasped the work of the four men previously mentioned and in his *Principia* performed a major synthesis of terrestrial and celestial mechanics made valid by his penetrating use of mathematical logic, including the rudiments of the calculus, which he devised for his purposes. The magnitude of this step can scarcely be overestimated: it showed the wide validity of physical principles and their extension by the law of gravitation to regions far beyond the earth; it removed all boundaries to man's attempts to apply new-found ideas; and, by the many deductions and predictions drawn from the laws of motion, it gave increased confidence in the power of mathematical theory when applied to measurements in the physical world. Newton's laws of motion, in part anticipated by Galileo, were clear guides to all subsequent studies of motion.

The law of gravitation provides an elegant example of what may be called a useful theory. Aside from its impact on philosophy and theology, it illustrates what a good theory should do. First, it took into account and employed quantitatively all relevant prior knowledge and observation. For example, Newton showed Kepler's first and second laws to be characteristic of a motion taking place with conservation of angular momentum under a centrally directed force acting between a planet and the sun. The third law was shown to be a necessary consequence of an inverse square law of gravitation, when applied to the motion of an object moving in a curved path; this was in accordance with the Dutch mathematician, astronomer and physicist Christiaan Huygens' then recently stated (1673) law of centripetal force. Second, Newton's work led to the solution of several baffling problems of long standing—problems to which it was not originally directed—such as the cause of the tides and the orbits of comets. Newton pointed out the necessary oblateness of the earth because of its rotation, a fact then not even suspected, and proceeded to employ the existence of this equatorial bulge to explain the slow precession of the equinoxes. Finally, under constant testing, the *Principia* and its various descendants in mathematical deduction led to a fuller understanding of motion of all kinds. The new ideas of relativity superseded Newton's only in the case of velocities approaching the speed of light. Newtonian mechanics could thus still be regarded as a good first approximation to the more general mechanics of relativity.

The full mathematical development of Newton's mechanics took place in the 18th century, culminating in the publishing in France of J. L. Lagrange's *Mécanique Analytique* (1788) and the *Mécanique Céleste* (1799–1825) of P. S. Laplace. In these works, the implications of gravitational potential and the principle of conservation of mechanical (potential and kinetic) energy played a leading part; and they provided a firm foundation for the subsequent bringing of all forms of energy into the more general conservation principle of the 19th century. Application of Newton's law of gravitation to the detailed examination of planetary motions led, in one memorable triumph, to the discovery of the planet Neptune independently by U. J. J. Leverrier in France and by J. C. Adams in England in 1846. Finally, discrepancies in the precession of the

perihelion of the planet Mercury, whose motion did not completely satisfy Newtonian mechanics, was a source of discomfort to astronomers until the German-born Albert Einstein (then of Berne, Switz.) removed most of the observed discrepancy by application of his relativity theory (1905). Hence, in numerous steps, of which the foregoing are but a few important examples, physics advanced to a fuller understanding of mechanics, both terrestrial and celestial, by the interplay of observation, laboratory experiment and theoretical deduction. Discrepancies between theory and observation, however small, often were the guide to new experiments which in turn were the source either of new discoveries or of a revision of basic ideas in the conceptual framework of thinking.

The Electrical Nature of Matter.—A second example of how physics progresses is the growth of the atomic view and its extension to the atomicity of electric charge, from which base the development of nuclear physics proceeded. The chemical experiments of John Dalton of Manchester, Eng., in the first decade of the 19th century laid the experimental foundation for the concept of atomic weight. Rapidly, throughout the 19th century, there grew the idea of a limited number of elements which could combine in an almost limitless number of ways to form chemical compounds—outward complexity with an underlying simplicity. The periodic system of the elements as formulated by the Russian chemist D. I. Mendeleyev served as a framework for the few scores of elements known. In mid-19th century there arose the kinetic theory of gases, which successfully attributed such phenomena as the pressure and viscosity of a gas to the motions of myriad submicroscopic atomic and molecular particles. This theory did much to bring quantitative measurement to bear upon invisible particles and their motions, and it assisted in bringing thermal phenomena firmly within the scope of the newly enlarged principle of conservation of energy. J. Clerk Maxwell of Scotland and Ludwig Boltzmann of Austria, among others, gave the kinetic theory extensive mathematical form, and produced an expression for the molecular velocity distribution function that in subsequent years was verified experimentally.

By 1895 the growing weight of chemical evidence and the success of the kinetic theory in dealing statistically with large numbers of particles left little doubt that atoms and molecules were real. Whatever doubt remained was in large part dispelled by Einstein's analysis and Jean Perrin's experiments in France on the Brownian movement, the random motions of microscopic particles, which had remained unexplained for 80 years. Near the turn of the century, physicists were on the threshold of several significant discoveries which stemmed from experiments on the passage of electric current through gases at low pressure and from the study of optical spectra which, since the work of R. W. von Bunsen and G. R. Kirchhoff in Germany in 1859, had played a prominent part in chemical analysis. An important question persisted: how could simple atoms give rise to such complex spectra as were found? These characteristic spectra must in some way be connected with the structure and inner properties of atoms. In approximately 20 years, several strands of the tangle were unraveled, principally from the discovery of the electron.

The electron, or corpuscle of negative electricity, was the first subatomic particle to be identified as a constituent of all atoms. It was shown by Sir J. J. Thomson of England, in his studies of cathode rays, to have the same ratio of charge to mass, e/m (1.76×10^8 coulomb/gram), regardless of the element from which the rays were derived. Thomson showed by deflecting cathode rays with electric and magnetic fields that this e/m was 1,837 times greater than e/m for the lightest known substance, hydrogen, as measured by electrolysis. The presumption was strong that this swift new-found particle bore the same charge but had only $1/1,837$ the mass of the hydrogen atom, a surmise that has stood the test of experiment. The subsequent measurement of the electronic charge by Robert A. Millikan (then of Chicago) in his well-conceived oil-drop experiments (1909–16) demonstrated the definiteness of this charge, now stated as -4.80×10^{-10} E.S.U., regardless of the source of the electrons. Millikan's work showed that all electric charges, whether positive or negative, must be regarded as composed of these definite small charges, and that electricity instead of

being infinitely divisible has an atomic nature. The English chemist and physicist Michael Faraday (1791-1867) had approached this position by his experiments in electrolysis many decades earlier, and his work now returned to prominence as, with knowledge of the charge on an ion in electrolysis, it became possible to compute with accuracy Avogadro's number, the important number representing the aggregate of atoms in a gram-atom, measured to be 6.0228×10^{23} .

At almost the same time that Thomson was measuring e/m for electrons, W. Röntgen of Germany found the penetrating radiation which he called X-rays. These rays were generated by the sudden stopping of cathode rays or electrons upon impact with metal targets. Thus, the electron was demonstrably connected with the emission of radiation. It was suspected that this agile particle might be the source of atomic spectra but three important steps had to be taken to prove this connection. These were in turn the discovery by Max Planck of Germany of the quantum nature of radiation, the discovery of the nuclear atom by Sir Ernest Rutherford of Great Britain and the synthesis of a suitable atomic model by Niels Bohr of Denmark. It was shown by Planck in 1900 from his theoretical studies of thermal or "black body" radiation that light must be considered not as transmitted by energy infinitely divisible, as had been previously assumed, but rather as being emitted and absorbed in small bundles of energy which he called quanta. The magnitude of a quantum or photon he showed to be $h\nu$, where ν is the frequency of light and h is a constant of action or energy $\times$ time ($6.6252 \pm 0.002 \times 10^{-27}$ ergs $\times$ sec.), which Planck introduced into physics and which appears to be one of the fundamental atomic constants. In this way was born the quantum theory which, with its descendant, quantum mechanics, became indispensable to the understanding of atomic and nuclear phenomena.

The early quantum theory was given considerable assistance by Einstein, who adopted it in explanation of the photoelectric effect. In his important 1905 equation, Einstein showed that the maximum kinetic energy of an electron ejected by light from a metal could be expressed by $\frac{1}{2}mv_{max}^2 = h\nu - \phi_e$ where $h\nu$ is, as before, the energy of the photon and ϕ_e represents work done to assist the electron across the potential barrier of the metal. This equation made no pretense of supplying a detailed mechanism for the potential barrier nor for extraction of electrons from metals, yet it was based firmly upon the concept of energy conservation. As of the latter 1950s it had been successful in every experimental test to which it had been put, ranging from the infra-red region of the spectrum to gamma rays.

Also, late in the 19th century A. H. Becquerel, Pierre and Marie Curie (all of France) and Rutherford were leaders in the exploration of radioactivity. These studies were destined to lead to the discovery of other subatomic particles and to the whole field of nuclear physics. In examining the growth of atomic theory, the discovery of the atomic nucleus by Rutherford (1911) is the most relevant matter. From the scattering of swift alpha particles from radioactive substances as these particles were directed against thin metal foils, such as gold leaf, Rutherford concluded that the alpha particles often encounter strong centres of repulsion and that most of the mass and the positive charge of the gold atoms must be concentrated in a small region less than 10^{-12} cm. in diameter. If, as became apparent from these experiments, the positive charge was concentrated in a small nucleus, each neutral atom could be regarded as having positive and negative charges of equal magnitude, each charge being an integral number of the fundamental electronic charges. Both the scattering experiments and contemporaneous experiments on the X-ray spectra of metals conducted by H. G. J. Moseley in England in 1913 showed that this positive charge on the nucleus is Ze where Z is the atomic number or ordinal position of an atom in the periodic table of Mendeleyev. Hence a neutral atom must have Z electrons also. The atomic number was recognized as the sure indicator of the chemical element to which an atom belongs, whereas it had become abundantly evident in the discovery of isotopes that atomic weight is a less definite indicator. This field of isotopes, so important to both chemistry and physics, will be discussed later.

In view of the definite photon energy represented by each line

in the spectrum of an atom, Bohr was led in 1913 to postulate a large but finite number of recognizable energy states for electrons in atoms, with the transition of an electron from one state of energy to another of lower potential energy as the source of each photon. Inasmuch as the number of such possible transitions is large, the number of spectral lines is likewise large for a given type of atom. Thus a comparatively simple mechanism was again proposed to explain the complex spectral emission of even the simplest atoms. Bohr's theory of atomic structure, whatever its limitations, is a good example of the application of basic physical principles. Central in Bohr's treatment was the quantization of angular momentum, from which the quantization of the energy of photons erupted as a consequence. Bohr postulated a number of "stationary energy states"—states of comparative performance only—which electrons could occupy in the atom. These were limited to those mechanical orbits of electron rotation about the nucleus characterized by angular momentum $n\hbar/2\pi$, where n is an integer now called a quantum number and $\hbar$ is Planck's constant. Energy exchanges were considered to occur as follows: in order for an atom to emit radiation it must first be excited or receive energy by impact, thermal or electrical, or by the absorption of other radiation. Bohr viewed this as the forcible removal of the electron to a greater distance from the nucleus to which it was bound electrostatically. As the electron settled down from such an excited state, it would emit one or more quanta of radiant energy by one or more successive transitions between energy states. The total energy emitted by the atom in returning to its lowest state of potential energy was thus set equal to the energy originally absorbed. Bohr's model by the 1950s was mostly of historical interest, but the quantization of angular momentum, the concept of energy states, the emission and absorption of definite quanta of energy in transitions of electrons from one state to another—all these remained. It was necessary to modify the idea of orbits and to revise the system of quantum numbers in favour of a wave-mechanical view that fit the observed facts of spectroscopy better. The work which Bohr did in synthesizing the available knowledge of the time was comparable with that performed by Newton in the earlier illustration; he united into a coherent system the quantum emission and absorption of radiant energy, the basic ideas of conservation of angular momentum, conservation of energy and the balance of electrostatic and mechanical forces. From the simplified view which evolved, he was able to account for the spectrum of hydrogen, the simplest atom. Experimental checking of the consequences of his theory led to the discovery of certain series of lines in the hydrogen spectrum and in the spectra of hydrogen-like atoms (singly ionized helium, doubly ionized lithium, etc.) consistent with theory. A decade or more of intensive research into optical spectra was stimulated by the application of quantum ideas. As experimental evidence piled up, significant discrepancies were apparent in the Bohr model, but the way to modify it was not immediately at hand; when a change came it was in a form more sweeping than expected, as the older quantum notions of Planck, Einstein and Bohr gave way to the new quantum and wave mechanics of Werner K. Heisenberg of Germany, Erwin Schrödinger of Austria, the German-born English physicist Max Born and P. A. M. Dirac of England. (More will be said of this in later sections.)

In both of these extended examples, there were certain similarities in procedure. Experimental evidence sometimes led theory, as in Kepler's laws of planetary motion or Faraday's laws of electrolysis. At other times the reverse was true, and theory led to new experiments. The final arbiter is experiment, and physicists are accustomed to relinquish even attractive theories when they are found to be at variance with clear experimental evidence. Relativity surpassed Newtonian mechanics, and quantum mechanics surpassed the earlier quantum theory from which it came. In both cases, discrepancies between observation and theory prompted the change to a more comprehensive view; and in each case the result was a more productive theory that gave direction to new experiments.

It may be observed in closing this account of the electrical nature of matter, illustrated strongly by the identification of the electron, that the electron soon after its discovery offered one of the earliest

and best evidences for the variation of mass with speed, as inferred from the theory of relativity. Thomson's early measurements of e/m were followed by others made by Walter Kaufmann and A. H. Bucherer of Germany that showed e/m to decrease with increase of speed of the electrons. This variation was properly attributed to an increase in mass of the electron and was shown to be in good experimental agreement with the equation $m =$

$$\frac{m_0}{\sqrt{1-v^2/c^2}}$$

as specified in the relativity equations by Einstein;

where m_0 is the rest mass, v is the velocity of the particle and c is the speed of light. The observations just reported throw light also on another aspect of development in physics, namely the growing coherence of scientific knowledge: here can be seen a close link between the forefront of knowledge in mechanics, as given in relativity, and the details of atomic structure as met in the study of the electron.

At this point, we shall leave these historical examples to treat recent developments in physics under five headings: radiation; atomic and nuclear structures; solid state physics; some major areas of theory; and instrumentation.

Radiation.—Examining the interactions of radiant energy with matter serves to give a better understanding both of matter and of light and its allied radiations. This two-way traffic is well illustrated in the case of X-rays, where the discoveries of the nature of the rays and of the nature of matter struck by them were complementary. From the early conjectures of Huygens, who viewed light as a wave motion, and of Newton, who viewed it as corpuscular, the view in the latter 1950s was of an inseparable duality, although certain experiments accented one characteristic more than the other. The wave aspect gained pre-eminence during the 19th century from the experiments (1811) of T. Young of England, who showed interference of two light beams, best interpreted as evidence of waves. A. J. Fresnel of France extended Young's treatment, discussed diffraction phenomena and formulated a detailed wave theory which was the forerunner of the elegant electromagnetic theory of J. Clerk Maxwell. The discovery of electromagnetic waves by the German physicist H. R. Hertz and the subsequent development of wireless, radio and radar reinforced Maxwell's theory and extended the electromagnetic spectrum from the infra-red end of the optical region to waves thousands of metres long. At the other end of the spectrum, diffraction effects were used to identify the very short wave lengths (about 10^{-10} cm.) of X-rays and gamma rays. However, the high-frequency end of the spectrum gave inescapable evidence for the photon or quantum nature of the radiation. (The interpretation of spectra on the quantum basis has been introduced above.)

Advances in instrumentation in spectroscopy became significant as greater precision in wave-length measurement and greater resolving power gave the necessary numerical evidence to implement the quantum view. Massive accumulations of precise data in optical spectra were made, as in the *M.I.T. Wavelength Tables* compiled by G. R. Harrison of Cambridge, Mass., and others. The Zeeman effect, which was discovered at the time when Thomson was measuring e/m for electrons, gave evidence that a particle of the same e/m was present in the splitting of spectral lines from a source situated in a strong magnetic field. The refined extension of Zeeman spectra when combined with the Pauli exclusion principle (see below) did much to permit a complete description of the outer electronic architecture for all of the electrons in atoms throughout the periodic table. Thus, the details of the electronic structure of matter could be considered as reasonably complete.

X-ray spectroscopy, particularly the study of X-rays characteristic of each element, showed how the inner electrons of an atom's electronic cloud are disposed and, through the work of the English physicist H. G. J. Moseley, showed additional evidence for the validity of atomic number as the determining factor in element identification.

Two further experimental developments in radiation will be reported because both contributed to the rise of quantum mechanics. The first is the photoelectric effect mentioned above, which gave clear evidence of the absorption of radiation in definite energy

bundles and the transfer of this energy to the ejection of a single electron. More recently, nuclear photoeffects were discovered by the ejection of neutrons, protons and mesons from nuclei, and by the photo-disintegration of light nuclei under the impact of gamma rays, further showing the validity of the energy quantum aspect of electromagnetic radiation. The experiments in 1922 of Arthur H. Compton, then of St. Louis, Mo., on the ejection of electrons from atoms by X-rays, and the accompanying modification of the wave length of the X-rays scattered in the process, appeared likely to remain significant as clear evidence for the ballistic impact of photons on electrons to which the conservation principles of momentum and energy have been applied in detail. The extension of these principles into the atomic and nuclear regions gave added confidence in their extraordinary range of validity. The Compton effect subsequently was extended to the scattering of visible light and the slight modification of wave length accompanying such scattering, as shown in 1928 by C. V. Raman in Calcutta.

Perhaps the most remarkable offspring of these experiments was the postulation of particle waves in 1924 by Louis de Broglie of France, who considered that if a photon which has demonstrable wave properties can also show such ballistic properties, a "particle" (such as an electron, proton, neutron, etc.) may show wave properties. This extension of the dual nature of wave and corpuscle in radiation to a similar duality in particles produced extensive results in both theory and experiment. The wave mechanics which sprang from it are described below. Diffraction effects for electrons (C. J. Davisson and L. H. Germer of the U.S., G. P. Thomson of England, S. Kikuchi of Japan), for protons (O. Stern, then at Hamburg) and for neutrons (E. O. Wollan and C. G. Shull of Oak Ridge, Tenn.) showed the experimental validity of De Broglie's bold suggestion. This is an example of what may be called reversibility of effects, a viewpoint or policy of investigation that has frequently guided physicists to the discovery of converse effects.

The final item under radiation is a brief examination of cosmic radiation—a mixture of electromagnetic radiation and swift particles. The study of cosmic radiation resulted in fruitful by-products that were not expected when it began. In an effort to trace the cause of leakage of electric charge in a well-insulated electroscrope, first J. C. McLennan of Canada, then Millikan, following the earlier experiments of V. F. Hess of Austria, sent electroscopes aloft in balloons and verified Hess's discovery that, contrary to expectation, the leakage increased with elevation. This suggested a source of ionization high in the atmosphere; and as subsequent world-wide observation showed, the radiation causing the ionization was entering from beyond the earth and was not intimately connected with the sun, as shown by lack of pronounced day and night or seasonal variations. The origin of these rays called cosmic (so named by Marie Curie of France) is not known, but they appear to be due primarily to very high energy atomic particles (e.g., protons) which in turn may generate electromagnetic waves and mesons when they collide with atoms high in the atmosphere. The energy of the primary particles is great, often in excess of 10^{18} ev.

Directly from cosmic ray studies came the detection by Carl D. Anderson at Pasadena, Calif., of the positron or positively charged electron (1932), and of mesons (Anderson and S. H. Neddermeyer). Electron-positron pair formation was also observed as important evidence that radiant energy could be converted back into mass with conservation of mass-energy. Physicists learned to copy nature by bringing high-energy reactions under laboratory control. These efforts surpassed the most energetic reactions of natural radioactivity but they still fell far short of the more energetic cosmic ray effects. The laboratory generation of mesons and of antiprotons (negatively charged protons) were among the successes achieved by laboratory means. Cosmic rays offered a stern challenge to the experimenter to devise means for measuring energy bundles far greater than those encountered earlier, and means for differentiating between photons and energetic particles moving near the speed of light and made massive by their enormous energies according to the $E = mc^2$ relation.

Atomic and Nuclear Structure.—It has been seen how the discovery of the electron and the pursuit of spectroscopic knowledge led to the idea of specific energy levels characteristic of atoms. This section first looks further into electronic structure, then more deeply into nuclear structure as represented by radioactivity, natural and induced, isotopes and nuclear reactions; it concludes with a resumé of the "particles" of physics as viewed in the latter 1950s. Additional evidence other than spectroscopic for electronic energy levels came in 1913 from the study of excitation and ionization potentials by electron bombardment (J. Franck and G. Hertz, then of Berlin), wherein atoms were shown to receive energy in inelastic collisions. The ionization potential of an atom (expressed in electron volts) indicates the minimum energy which must be given to the least tightly bound electron to extract it completely. It is greatest (24.5 ev) for helium and least for the alkali metals (e.g., caesium, 3.87 ev). Electrons may likewise be removed by the absorption of photon energy of suitable magnitude, as in X-ray absorption. Studies of these effects contributed much to the allocation of electrons to specified shells as described below.

For many elements, further ionization potentials were known, signifying the energies required to extract the second, third, etc., electrons from an atom. The chemical inertness of the noble gases—helium 2, neon 10, argon 18, krypton 36, xenon 54 and radon 86—and the chemi-

cal activity of the alkali metals next above them in the periodic table of the elements—lithium 3, sodium 11, potassium 19, rubidium 37, caesium 55 and francium 87 (not as fully studied as the others since no stable isotope had been found)—were suggestive of the part played by electrons in the chemical bond, a matter pursued by Linus C. Pauling of Pasadena, Calif., and others. The inert gases were regarded as important division points in the periodic system where successive electronic shells become filled and atoms become electronically "satisfied." These shells took their designation from the underlying similarity of X-ray spectra which arise from the disturbance of inner electrons, being in order from the nucleus outward called K, L, M, N, O and P. The number of electrons in successive completed shells is 2, 8, 18, 32, 18 and 8; which were the same numbers "allowed" by detailed application of a principle stated by the Austrian-born physicist Wolfgang Pauli (then of Zürich), that no two electrons are to be described by the same set of quantum numbers. The elements next above each of the noble gases have one additional electron, called a valence electron, which apparently plays the major role in its chemical behaviour. (For a fuller explanation of electron structure, see SPECTROSCOPY and SPECTROSCOPY, X-RAY.)

Looking beyond the electron configuration, it has been seen how Rutherford discovered the atomic nucleus by alpha particle scattering. To examine nuclear structure, radioactivity and some of the ideas that have stemmed from it should first be considered. Radium, the classic example of an unstable element, spontaneously gives off swift alpha particles and becomes a new element, radon or radium emanation, element number 86 and the heaviest of the noble gases. Rutherford identified the alpha particle as the nucleus of the helium atom of mass 4 and charge + 2e, designated ${}^4\text{He}^+$. Hence, its ejection from the nucleus transfers radium from mass 226 to mass 222, and from atomic number 88 to 86, meaning that a neutral atom of radon would have 86 electrons distributed in six shells as follows: 2K, 8L, 18M, 32N, 18O and 8P. Some substances emit beta particles, identified as swift electrons. Loss of a beta particle from the nucleus enhances the net positive charge by one electronic unit and causes the substance to rise one in the scale of atomic numbers; but, as the electron is so light, no change in mass number is assigned.

Most radioactive substances also give off penetrating gamma rays, the more energetic, shorter wave length and higher frequency cousins of the X-ray, giving evidence of a settling down of the nucleus from an excited state (in the manner of electron settling in the emission of optical spectra, but with far greater energy). Much effort was spent in identifying distinct nuclear energy levels by gamma ray spectroscopy. Each of the 40 or more natural radioactive types was identified by the energy of the rays and particles emitted and by its half life; i.e., the time in which half of its atoms transmute into some other type. Half lives range from a few ten millionths of a second to a few thousand million years. As the many radioactive species, generally grouped in four families springing from the slowly decaying ancestors—uranium, thorium, actinium and radium—must all find their places within a range of atomic numbers from 94 to 82, it became evident that there was a crowding of atoms of different atomic weight in the same positions in the table. Thus arose the concept of isotopes; i.e., atoms of different mass but of similar chemical nature and atomic number.

Isotopes were also found among nonradioactive elements throughout the periodic table, starting with the discovery by J. J. Thomson (1913) of isotopes of neon and chlorine. Thomson demonstrated that the chemical atomic weights of neon (20.2) and of chlorine (35.46) were the result of mechanical mixtures of isotopes with atomic weights of 20 and 22 in the case of neon, and 35 and 37 in the case of chlorine. From this sprang much activity in the field of mass spectroscopy with F. W. Aston of England and A. J. Dempster, K. T. Bainbridge, A. O. Nier and M. G. Inghram of the U.S. as major contributors. One importance of mass spectroscopy lies in its usefulness in finding increasingly precise values of atomic masses, information important in the detailed balancing of energy in nuclear equations. About 1,000 or more atomic types allocated to approximately 100 elements were known to exist in the latter 1950s. Many of these were radioactive (see below).

An important conclusion could be drawn from the precise knowledge of atomic masses as supplied by mass spectroscopy; namely, evidence of the binding energies of the atomic nucleus. This evidence appeared first in Aston's so-called packing fraction curve which demonstrated a decrease in mass among atoms of progressively higher atomic number if they were considered to be made up of protons (and, later, neutrons). For example, if 16 protons (or their equivalent in mass) were to unite to form one oxygen atom (mass 16.000 as the basis of the atomic mass scale) there would result a decrease in mass of 0.128 atomic mass units, equivalent to a decrease in energy of 120 Mev (million electron volts). Energy of this amount may be considered to have been released on formation as kinetic energy and gamma radiation; and a similar amount would be required to restore the oxygen atom to its original constituent particles, now regarded as eight neutrons and eight protons. The implications of Aston's curve were clear: among the lighter elements, consolidation (fusion) would lead to significant energy release; as also among the heaviest elements, splitting into smaller components (fission) would release energy. Both of these effects were shown to exist in the large scale release of nuclear energy.

The discovery in 1919, by Rutherford, Sir James Chadwick and Sir Charles D. Ellis of Cambridge, Eng., of the ejection of protons (hydrogen nuclei) from nitrogen atoms when bombarded with alpha par-

ticles led directly into a vast region of nuclear physics and chemistry somewhat indicated by Aston's curve. The equation of this first observed nuclear reaction is worthy of examination:

Subscripts designate atomic numbers, superscripts show mass numbers on the basis of oxygen 16; Q represents energy change on the mass-energy basis. In this case a net decrease of mass of 0.0082 atomic mass units signifies an increase of kinetic energy of 7.6 Mev, so the reaction is exothermic and releases energy.

Another important reaction which proved to be the key to countless others was that accompanying the discovery of the neutron (g.v.) by Chadwick (1932) while he was attempting to interpret the strange effects reported by W. Bothe and H. Becker of Germany and by Frédéric and Irène Joliot-Curie at Paris. In these experiments, alpha particles striking beryllium were found to eject radiation of great penetrating power. Chadwick showed by the recoil ejection of protons when struck by this radiation that, by postulating a new particle with no electric charge but with mass comparable with that of the proton, all observed effects could be accounted for.

The equation for the reaction was:

There also had been success in causing nuclear disintegrations by high-energy protons, as in the work of the physicists Sir J. D. Cockcroft of England and E. T. S. Walton of Ireland, high energy being needed to cause the proton to overcome the electrostatic repulsion of the bombarded nucleus. Neutrons do not encounter adverse electrostatic repulsion as protons do; hence they can drift into nuclei even at low speed and upon entry they can bring about hundreds of nuclear reactions, as was early shown by Enrico Fermi and his collaborators in Rome, by the Joliot-Curies and by others.

A further outcome of alpha particle (and later neutron) bombardment was the discovery of induced or artificial radioactivity, or the ability to render nuclei unstable and truly radioactive by bombardment. The original experiment was performed by the Joliot-Curies (1934), who bombarded aluminum with alpha rays and found a reaction as follows:

Here P^* indicates radiophosphorus which decays with half life of 195 sec. into silicon, with the ejection of a positron, designated ${}^0\text{e}^0$ to indicate unit positive charge but negligible mass. As a result of this initial observation, and the subsequent discovery of neutron-produced types, many hundreds of radioactive tracer elements became available for experimental work in medicine, agriculture, biology and chemistry. The particular virtue of radioactive tracer atoms is that chemically they are indistinguishable from normal atoms, yet their presence can be detected by radiation counters. (See Instrumentation below.)

The finding of the neutron simplified the concepts of nuclear structure, as only protons and neutrons were needed to satisfy theoretical requirements. The possibility of electrons in the nucleus could be dismissed on theoretical grounds by Heisenberg's principle of uncertainty as they are too big to fit into the small space afforded. The ejection of beta particles from the nucleus was regarded in the latter 1950s as due to the formation of the electron at the instant of ejection when a neutron turns into a proton; similarly, positron emission was evidence of a proton becoming a neutron.

The neutron also played a prominent part in the release of nuclear energy from uranium and plutonium by the process called fission, with explosive violence in the nuclear bomb or at a slower, controlled rate in the nuclear power reactor. Slow neutrons caught by U^{235} or by Pu^{239} caused these atoms to split into fission fragments of intermediate atomic mass with a large release of energy. At the same time, additional neutrons were released and were able to produce new fissions in available material in a self-sustaining reaction.

Three fundamental stable particles sufficed for the rudimentary structure of the atom. For any given type of atom of mass A (basis oxygen 16) and atomic number Z, views in the latter 1950s called simply for a nucleus composed of Z protons and N neutrons so that $Z+N=A$. There were also required in a neutral atom Z electrons to balance the nuclear charge + Ze. Neutrons which when free are radioactive with a half life of about 13 min. are, for some unknown reason, stable when bound in the nucleus. Photons may be regarded as particles of zero rest mass which act as carriers of bundles of energy from atom to atom, existing only until their mission is accomplished, even though this may take millions of years, as in the case of stellar radiation. There are a number of other particles whose transitory existence was demonstrated in the late 1940s and 1950s. Neutrinos are ephemeral neutral particles postulated as necessarily ejected in cases of beta particle emission and in meson disintegration. Were it not for the quite convincing experimental evidence of their existence by F. Reines and C. L. Cowan of Los Alamos, N.M., and others, one might regard neutrinos as the necessary but undetectable scapegoats whose subtle function was to permit the application of conservation of energy and momentum to atomic reactions.

A number of other particles of exceedingly transitory yet demonstrated existence were found in cosmic ray and high energy accelerator research. The function of most of these was not yet understood as of

the mid-1950s. Only the mesons seemed to serve in binding nuclei together in a way analogous to the binding of atoms into molecules by electronic forces. The catalog of particles with their masses given in terms of electron masses included neutrinos, 0; positive and negative electrons, 1; positive and negative mu-mesons, 207; positive, negative and neutral pi-mesons, 270; neutral, negative and positive K-particles, 966; neutrons, protons and antiprotons, 1,837; neutral lambda particles, 2,182. Those more massive than the neutron and proton are called hyperons. The antiproton generated by the bevatron and studied by Emilio Segrè and others at Berkeley, Calif., was the expected negative counterpart of the proton, just as the positron was anticipated by Dirac before its discovery by Anderson. (See PARTICLES, ELEMENTARY.) The phenomenon of positron-electron pair production requires gamma ray energy at least as great as the self-energy of two electrons, or 1.02 Mev. Antiproton-proton pair production requires 1,837 times this energy. When antiproton and proton meet they annihilate one another with liberation of their self-energy, as detected in numerous meson stars produced in photographic emulsions.

Solid State Physics.—Atomic physics proceeded most rapidly as it dealt with matter in a highly dispersed state, as in gases at low pressure. Matter in the solid state presented a challenge which was being met in the latter 1950s in experimental and theoretical studies of solids. Much data in this field was gathered through the years as useful engineering information on the elastic, thermal, electrical, magnetic and optical properties of materials. Physics at mid-20th century was attempting to explain these properties and hoped eventually to predict them from knowledge of atoms and their interactions. To this end, the tools of the physics laboratory were used to study crystal structure by X-ray and neutron diffraction, to create single crystals of very pure substances under carefully controlled conditions, to show the effects of small but controlled amounts of impurities on the properties of metals, and to seek the properties of plastics, ferrites and semiconductors. The knowledge of low-temperature performance of metals (near 0° K.), including the phenomenon of superconductivity, allowed an increasingly effective application of quantum mechanics to atomic and molecular aggregates.

Theory.—It is unlikely that physicists will rest from their labours so long as ignorance about the forces of nature remains. One of the major theoretical endeavours is to gain a more unified view of the several forces which exhibit themselves, as in the gravitational attraction between large masses even at very great distances; the magnetic and electrical forces evident between objects at distances from atomic to terrestrial; the molecular forces between atoms and molecules appreciable from 10^{-8} to 10^{-6} cm.; and the extremely strong but short-range forces which hold nuclear particles together, strong at 10^{-12} cm. but dwindling rapidly at greater distances. None of these forces was fully understood as of the 1950s, and even less was known of the relationship between them. For the binding of atoms into molecules, "electronic exchange" forces were postulated; for the binding of nucleons (protons and neutrons) in nuclei, "mesonic exchange" forces. By analogy, but with little experimental evidence for their existence, gravitons were postulated for gravitational forces.

Calculus and differential equations, ably assisted by more elementary mathematics and by vectors and matrices, may be said to be the mathematical language of physics. Newton is commonly regarded to share with the German mathematician G. W. Leibniz the invention of the calculus, a system of computation which he needed to solve in detail the problem of the gravitational attraction between two moving and approximately spherical bodies such as the sun and a planet. Differential equations were developed and applied with signal success to the formal growth of mechanics, wave motions and problems of the gravitational field. As electricity and magnetism developed experimentally, they were given systematic treatment by Maxwell, who demonstrated the close relationship between electromagnetic phenomena and light. H. R. Hertz's discovery of electromagnetic waves based thereon led, through the engineering development of electronics, into the arts of radio, radar and television. Other major theoretical developments of the second half of the 19th century were thermodynamics and statistical mechanics. The first gave broad form to the relation of heat to other forms of energy and raised the principle of conservation of energy to a pinnacle; the second treated the mechanics of large numbers of particles and joined the mathematics of probability firmly with physical ideas, as in the kinetic theory of gases and, in the hands of J. Willard Gibbs of New Haven, Conn., extended thermodynamics to the field of chemistry.

Each new and promising burst of theoretical ideas was followed by a period of extended testing as these ideas were applied to a widening array of phenomena and, as usually happens, limitations were found at some point. Thus, thermodynamics reached a barrier when applied to the study of wave length distribution of radiant energy from hot bodies, a field for which it was hopefully deemed adequate. Only by Planck's drastic assumption of energy quanta (mentioned earlier in this article) was a satisfactory escape shown. This new theory soon established a domain of its own where it demonstrated its superiority over thermodynamics, as in explaining the photoelectric effect (Einstein); specific heats of solids and gases (Einstein, then of Berlin, F. A. Lindemann of England and P. J. W. Debye, then of Berlin); the early interpretation of spectra (Bohr and the German-born Arnold Sommerfeld); and the scattering of radiation by electrons (Compton). Again, discrepancies

and new experimental evidences, particularly the demonstration of particle waves postulated by De Broglie, forced drastic modification in the earlier quantum ideas. There developed after 1925 the wave mechanics of Schrödinger, Heisenberg, Born and Dirac, augmented by the concepts of the spinning electron (the physicists S. A. Goudsmit and G. E. Uhlenbeck of the Netherlands), the exclusion principle (Pauli) and the uncertainty principle (Heisenberg).

The quantum mechanics demonstrated its right to displace earlier theories by its capacity to treat more accurately the evidence of spectroscopy, to recognize and utilize the wave-particle duality and to give a more complete explanation of radioactivity and nuclear structure than did its predecessors. By the mid-1950s considerable success had been attained in unifying the mechanics, electrodynamics and thermodynamics of 1890, and the quantum theory of 1920 (often called "classical") into a more comprehensive body of theory that covered an array of physical phenomena including many not even known at the earlier dates. Foremost in this achievement were relativity, quantum mechanics and quantum electrodynamics. Physicists weathered a number of shocks occasioned by the proposal of drastic new ideas and the need to discard earlier formulations. For example, experiments performed in 1957 at Columbia university, the Institute for Advanced Study at Princeton, the U.S. bureau of standards and The University of Chicago raised serious reconsideration of the idea of "parity," an idea which previously had been accepted without question. It may be said that both theory and experiment proceeding alternately step by step usually maintain a healthy state of mutual stimulation, justifying the special faith of the scientist that if he can only find the right question to ask the answer will ultimately be forthcoming.

Instrumentation.—Experimentation requires careful observation and quantitative measurement, there being nothing entitled to the name of science unless facts determined by measurement and expressible by number or symbols thereof can be set down. This implies the use of apparatus designed to bring a phenomenon under control, and instruments to measure the effects observed. Much of the progress in physics sprang from the development of meters and other devices to meet special needs. For example, vacuum pumps and high vacuum technique led to the industrial production of electronic tubes of many uses, especially in the field of communications. The cathode ray tube, so useful in television, radar and a host of other applications requiring quick response for the study of rapidly changing phenomena, came directly from the tubes that J. J. Thomson used in his early experiments on the e/m of electrons, already described. Electron optics, applied at first to the better focusing of electron beams, later found extensive use in the electron microscope, which surpassed by about 100 times the best optical microscope. The field of spectroscopy, with its triumphs in delineating atomic structure, made progress with the help of instruments of higher resolving power, especially when augmented by interferometers of the Fabry-Perot or Michelson type.

By the mid-1950s mass spectroscopy had progressed from the early mass spectrographs of Thomson and Aston to instruments of high resolving power by which the masses of isotopes could be compared with an accuracy of the order of 1 part in 10,000,000; and rare isotopes had been found by even more sensitive means of detection. These instruments employed a combination of electrostatic and magnetic focusing whereby ions were sorted specifically according to their mass. They added a new element of precision to the determination of atomic weights and contributed directly to the experimental validation of the important $E = mc^2$ equation.

Through the design of ultra-high-frequency generators such as the klystron and magnetron, microwave radio (in the 10,000-megacycle region) became important in radar systems in World War II; and these generators afterward found use in the extension of spectroscopy into the 1,000 to 10,000 megacycle region where molecular absorption and magnetic resonance phenomena were studied.

With the rapid growth of interest in nuclear physics, instrumentation likewise grew. For generating high-energy atomic particles, two chief kinds of accelerators became important: those that applied high voltage directly and those that gave charged particles successive increments of energy. Of the first kind were the electrostatic generator of the U.S. physicist R. J. van de Graaff and the voltage multiplier of Cockcroft and Walton. Examples of the second type were the linear accelerator and the cyclotron (E. O. Lawrence of Berkeley, Calif.) and its modifications—the synchrocyclotron, which extended the energy range by adjusting the period of acceleration of the ions to allow for relativity increase of mass with velocity; the cosmotron at Brookhaven National laboratory, Long Island, N.Y.; and the bevatron, the 6,000,000,000-ev accelerator, at Berkeley. Under construction in the U.S.S.R. in the 1950s was an accelerator of reportedly still higher energy. The betatron of D. W. Kerst (University of Illinois, Urbana), an electromagnetic induction accelerator for electrons, was successfully employed for generating electron and X-ray energies approaching 500,000,000 ev.

From its early function of producing nuclear fuels for explosive bombs, the nuclear "pile" or reactor came to be used as a power reactor in which nuclear fuels (uranium and plutonium) replaced coal and oil in the production of power, and as an experimental reactor in which the dense flux of neutrons was employed for producing nuclear reactions in substances exposed therein and from which neutron beams might be allowed to emerge for experimental uses.

The need for detection of nuclear particles led to the development of several important tools. Basically, detection was by photographic means, as in the original discovery of radioactivity by Becquerel, or by means of ionization effects produced by penetrating radiations and swift particles, as in the case of electrometers, ionization chambers, Geiger-Müller tube counters and the Wilson cloud chamber. In the last named, a combination of photography and ionization made possible the recording of evidence of the passage of swift particles, since they leave visible paths due to fog particles formed on ions which they produce in passing.

Four significant improvements on the original cloud chamber techniques of Wilson increased the chamber's effectiveness as a research tool: the use of magnetic fields to deflect charged particles and enhance the ability to identify them as to charge and momentum; the use of Geiger-Müller counters to control the chamber so as to photograph only those events for which the "trap is set"; the introduction of sheets of absorbing material, such as lead, within the chamber to study the penetrating properties of cosmic ray particles; and the modification of the chamber to the so-called bubble chamber in which ion paths were produced in liquid hydrogen near its boiling point. The bubble chamber, by the greater density of the medium in which tracks were formed, allowed a kind of compacting of the evidence into smaller space, a feature highly desirable in studying interactions of the very short-lived mesons with matter.

Electronic circuitry added much to the flexibility of the Geiger-Müller counter as an instrument for particle detection, inasmuch as automatic counting at high rates was made possible, and the counters could be connected to detect simultaneous events (coincidence counting) or to reject such events (anticoincidence). By treating the walls of the counter with a suitable material, or by introducing a suitable gas, such as boron trifluoride, a counter could be rendered sensitive to neutrons which by themselves leave no tracks and produce no ionization. The technique of employing photographic emulsions for the detection of nuclear reactions was, in a sense, an extension of the cloud chamber, inasmuch as ion tracks were permanently registered directly in the prepared emulsion. These could be studied at leisure under the microscope, thus bringing into the space of a few millimetres or centimetres the whole history of nuclear events caused by energetic cosmic ray particles or the mutual annihilation of positive and negative particles. (R. M. SN.)

PHYSIOCRATIC SCHOOL, a group of French political economists in the second half of the 18th century. Physiocracy (Greek *physis*, nature, *kratēin*, to rule) denoted the rule of nature; and the physiocrats envisaged a society in which natural economic and moral laws should have full play and in which positive law should be in harmony with natural law. They also pictured a predominantly agricultural society and therefore attacked mercantilism not only for its mass of economic regulations but also for its emphasis on manufactures and foreign trade. Whereas mercantilists held that each nation must regulate trade and manufacture to increase its wealth and power, the physiocrats contended that labour, trade and commerce should be freed from all restraint. Again, whereas mercantilists claimed that coin and bullion were the essence of wealth, the physiocrats asserted that wealth consisted solely of the products of the soil.

The origins of these ideas may be traced in numerous works, in France and in England, from the end of the 17th century; but the so-called Physiocratic school was founded by François Quesnay (q.v.; 1694-1774), a court physician. Despite a long residence at Versailles, Quesnay remained a countryman at heart, and his economic ideas were coloured by his early studies of Aristotle and Thomas Aquinas. Shortly after 1750 his rooms at the *Entresol* at Versailles became the meeting place of persons interested in economic and administrative problems. Among them was J. C. M. Vincent de Gournay (1712-59), but although this economist influenced Quesnay, he himself was never a physiocrat. Quesnay's first important disciple was Victor Riqueti de Mirabeau (1715-89), the author of *L'Ami des hommes* (1756, etc.), whom in 1757 Quesnay sought out and whom he convinced of his error in making population the source of wealth and in adopting too freely ideas from R. Cantillon's *Essai sur la nature du commerce* (1755). Mirabeau's admiration for Quesnay increased when he read the *Tableau économique*, which Quesnay had written for Louis XV in 1758. This work demonstrated, by happily chosen figures, the economic relationship between a workshop and a farm and purported to prove that the farm alone added to a nation's wealth. In 1759 Mirabeau published his *Explication du Tableau économique*, which was followed by his *Théorie de l'impôt* (1760) and *Philosophie rurale* (1763). These three works were an elaboration of

Quesnay's theories. In 1763 the young Pierre Samuel du Pont de Nemours (q.v.; 1739-1817) came to Quesnay's notice, and it is this event that marks the real beginning of the Physiocratic school, which was joined, among others, by P. P. le Mercier de la Rivière (1719-92), G. F. le Trosne (1728-80), the *abbé* Nicolas Baudeau (1730-92) and the *abbé* P. J. A. Roubaud (1730-91). As editor of the *Gazette du commerce*, Roubaud gave publicity to Quesnay's ideas. Baudeau controlled the *Ephémérides du citoyen* and, from 1766, put that journal entirely at the disposal of the school, which not only was supported by a faction at the court but also had provincial branches in certain of the societies of agriculture. Du Pont became virtually a party secretary. In 1767 he published under the title of *La Physiocratie* a collection of Quesnay's writings. This is the origin of the term "physiocracy," but Quesnay's following continued to call themselves *économistes*, the less ambiguous designation *physiocrates* not becoming current until the 19th century.

By 1768 the Physiocratic school was in decline. In 1774, however, shortly before Quesnay died, the hopes of both school and party were raised by the appointment of A. R. J. Turgot (q.v.) as comptroller general. Turgot himself was not a physiocrat; though he had affinities with the school, he was as much Gournay's disciple as Quesnay's and, like Gournay, did not accept the physiocratic thesis that industry was sterile. Nevertheless, the physiocrats rallied round him. But the enthusiasm of Turgot's supporters and a spate of physiocratic polemics in 1775 served only to give weight to the accusation that the government was in the hands of theorists. Turgot was dismissed in 1776 and the leading physiocrats were exiled; but Baudeau subsequently revived the school and kept it going till 1781.

Legal Despotism.—Like Pierre le Pesant de Boisguillebert (1646-1714), who had attacked J. B. Colbert's mercantilism, the physiocrats advocated the establishment of an *ordre naturel* in place of the existing order, which, they claimed, violated both the physical and the moral laws of the *jus naturale*. Society, they held, was a contractual union, not necessarily of equals in all respects, but of individuals who at least possessed equal natural rights and who by nature followed their own interests. These individual interests were, for the most part, identified in a natural way and led to no clash; but where the natural harmony was not possible, interests must be identified artificially—that is to say, by the action of government. Government, like society, they believed to rest upon consent; but as they considered it easier to enlighten the one than the many, they did not develop the democratic implications of their political theory but pronounced for enlightened despotism or, as they termed it, legal despotism.

Like many 18th-century thinkers, they were more concerned with the scope than with the machinery or form of government. They contended that the field of governmental action should be drastically reduced but that, where action was necessary, the government should act firmly, overriding sectional and perverted interests and enabling the laws of nature to prevail.

Produit Net and Impôt Unique.—Of all the natural physical laws none was more vital to physiocratic theory than that which pointed to the soil as being the unique source of wealth. Manufactures were useful, even necessary; but they merely gave natural wealth or materials a different shape. Manufacture did indeed raise the price of a commodity, but such an addition was merely the equivalent of the consumption of the manufacturer and not an increase in intrinsic value. Similarly, commerce merely circulated goods and products and made no addition to their value. Only where the merchant exported an unwanted surplus of agricultural products did he add to a nation's wealth. Had the physiocrats pondered more on this admission they might have been led, like Turgot, toward the problem of exchange value; but they did not conceive of an unwanted surplus as normal or as a likely development in agriculture, and they therefore remained steadfast in their belief that the soil alone yields a clear profit (*produit net*), or the gift of nature that remains after the cultivators have deducted from the yield their cost of living and have put by the seed for the next sowing. In his revised *Tableau économique* of 1766, Quesnay attempted to illustrate the *produit net* on a national scale.

He assumes a nation of 30,000,000 people, one-half of them being producers, one-quarter being proprietors and the remainder belonging to what he calls the sterile classes. The total money in the country is 3,000,000,000; of this, 2,000,000,000 is in the possession of the producers and 1,000,000,000 is in the hands of the sterile classes. With their 2,000,000,000 the producers get a return to the value of 5,000,000,000. Of this, 1,000,000,000 goes to replenish their fixed capital and 2,000,000,000 goes as *produit net* to the landlords, who exchange 1,000,000,000 for agricultural products and 1,000,000,000 for manufactured goods. The sterile classes obtain food and raw materials to the value of 2,000,000,000 and receive from the cultivators 1,000,000,000 in return for manufactured goods. Hence we are back where we started, and the cycle is repeated. This simplified picture ignored many of the features and the developments of the contemporary economic structure. It is moreover very obscure: it omits all mention of the consumption of manufactured goods by the manufacturing classes; it fails to explain how the sterile class obtains its capital; and it merely assumes and does not prove that the proprietors received the so-called *produit net*. But granted that assumption, it was logical to propose a single tax, the *impôt unique*, levied solely on the proprietors of land. It was here that Turgot agreed with the physiocrats, and it was this proposal which later found favour with the U.S. economist Henry George (1839-97).

Place of Physiocracy in Economic Thought.—Given their assumptions and the social system that they desired, the physiocrats were logical and systematic. What they did was to rationalize mediaeval economic ideals, employing to that end the more modern philosophical and scientific methods. Hence in their writings there is a strange blend of conservative and revolutionary thought and, to the modern mind, some inconsistencies. They asserted in a general way that prices were determined by cost of production and by supply and demand; but they assumed that there was a constant fair price (*bon prix*) which obtained under a regime of free trade. On the other hand, they claimed that government should fix the rate of interest. Again, they glorified tillage and lauded the cultivators but assigned the *produit net* to the landlords. No wonder, then, that the physiocrats have been variously regarded as levellers, as liberals and as feudal reactionaries. Their system did not survive for long. Their free-trade theories were, however, embodied in the Anglo-French commercial treaty of 1786 and in the decree of Aug. 29, 1789, freeing the corn trade. The land tax established by the constituent assembly on Dec. 1, 1790, also followed physiocratic precepts; but the issue of *assignats* or paper money in April 1790 ignored completely their theory of wealth. Indeed, this last theory soon ceased to hold respect. It had already been attacked by Adam Smith and was soon to be demolished by David Ricardo. Of greater importance than the conclusions of the physiocrats was their scientific method, which in other hands and in different circumstances was destructive of physiocratic doctrines.

PHYSIOGNOMY, a term which denotes a supposed science for the "discovery of the disposition of the mind by the lineaments of the body" (Sir Francis Bacon); it is also used colloquially as a synonym for the face or outward appearance, being variously spelled by the old writers.

Physiognomy was regarded by those who cultivated it as a two-

fold science: (1) a mode of discriminating character by the outward appearance and (2) a method of divination from form and feature.

The first systematic treatise that has survived is that attributed to Aristotle, in which he devotes six chapters to the consideration of the method of study, the general signs of character, the particular appearances characteristic of the dispositions, of strength and weakness, of genius and stupidity, of timidity, impudence, anger and their opposites, etc. Then he studies the physiognomy of the sexes, and the characters derived from the different features and from colour, hair, body, limbs, gait and voice. He compares the varieties of mankind to animals, the male to the lion, the female to the leopard. The general character of the work is based on analogical reasoning which may be gathered from the following specimen. While discussing noses, he says that those with thick bulbous ends belong to persons who are insensitive, swinish; sharp-tipped noses belong to the irascible, those easily provoked, like dogs; rounded, large obtuse noses to the magnanimous, the lion-like; slender, hooked noses to the eagle-like, the noble but grasping; round-tipped, retroussé noses to the luxurious, like barndoor fowl; noses with a very slight notch at the root belong to the impudent, the crow-like; while snub noses belong to persons of luxurious habits, whom he compares with deer; open nostrils are signs of passion, etc.

While the earlier classical physiognomy was chiefly descriptive, the later mediaeval authors particularly developed the predictive and astrological side, their treatises often digressing into chiromancy, onychomancy, cleidomancy, podoscopy, spasmotomancy and other branches of prophetic folklore and magic.

Along with the medical science of the period the Arabians contributed to the literature of physiognomy; notably Ali bin Ragel, Rhazes and Averroes. Avicenna also makes some acute physiognomical remarks in his *De animalibus*, which was translated into Latin by Michael Scot about 1270. Among mediaeval writers Albertus Magnus (b. about 1206) devotes much of the second section of his *De animalibus* to physiognomy. The famous sage of Balwearie, Michael Scot, while court astrologer to the emperor Frederick II, wrote his treatise *De physiognomia et de hominis procreacione*, much of which is physiological and of curious interest. It was probably composed about 1272 but not printed until 1477. This was the first printed work on the subject.

The 16th century was rich in publications on physiognomy. Treatises were published by, among others, John de Indagine, Cocles, Andreas Corvus, Michael Blondus, Janus Cornaro, Anselm Douxciel, Pompeius Ronseus, Gratatulus, Lucas Gauricus, Triacassus, Cardanus, Taisnierus, Magnus Hund, Rothman, Johannes Padovanus and, greatest of all, Giambattista della Porta.

The earliest English works were anonymous: *On the Art of Foretelling Future Events by Inspection of the Hand* (1504) and *A Pleasant Introduction to the Art of Chiromancie and Physiognomie* (1588). Thomas Hill's work, *The Contemplation of Man-kynde, Contayning a Singular Discourse After the Art of Physiognomie*, published in 1571, is a quaintly written adaptation from the Italian authors of the day.

The development of a more accurate anatomy in the 17th century seems to have diminished the interest in physiognomy by substituting fact for fiction. The principal writers of this age were T. Campanella, R. Coclenius, Clement, Timpler, J. E. Gallimard, Moldenarius, Septalius, Saunders, C. Lebrun (a precursor of Charles Bell), Elsholz, de la Bellière, F. Evelyn (in the appendix to *Numismata*), Baldus, Bulwer (in his *Pathomyotomia*), Fuchs, Spontoni, Ghiradelli, Chiaramonti, A. Ingegneri, Finella, De la Chambre, Zanardus, R. Fludd and others of less importance.

The 18th century shows a still greater decline of interest; the only name worthy of note is that of J. K. Lavater, *Essays on Physiognomy*, 4 vol. (1804). The popular style, good illustrations and pious spirit of his works gave them a popularity they little deserved, as there is no system in his work, which chiefly consists of rhapsodical comments upon the several portraits.

The physiological school of physiognomy was foreshadowed by Parsons and founded by Sir Charles Bell, whose *Essay on the Anatomy of the Expression*, published in 1806, was the first scien-

tific study of the physical manifestation of emotions in terms of the muscles which produce these manifestations. In the later editions of this essay the thesis is elaborated with greater detail. Moreau's edition of Lavater, in 1807, was somewhat along the same lines. The experiments of G. B. A. Duchenne (*Mécanisme de la physiognomie humaine* [Paris, 1862]) showed that by the use of electricity the action of the separate muscles could be studied and by the aid of photography accurately represented. The machinery of expression having thus been indicated, the connection of the physical actions and the psychical state was made the subject of speculation by Herbert Spencer (*Psychology* [1855]). These speculations were reduced to a system by Darwin (*Expression of Emotions* [1872]).

Illustrations of Darwin's theoretic propositions are to be found in the works of Bell, Duchenne and Darwin and in the later publications of Theodor Piderit, *Mimiké und Physiognomik* (1886), and Paolo Mantegazza, *Physiognomy and Expression* (1890), to which the student may be referred for further information.

The 20th century is characterized by empirical and quantitative investigations to determine the validity of general and specific physiognomic principles and generalizations. K. Pearson in 1906 laid the ax to the belief that head size and shape are related, to an appreciable degree, to intellect. He based his study on about 5,000 schoolchildren and university students. Sir Charles Goring in 1913 published his monumental biostatistical study of the validity of the Lombrosian system of criminal anthropology, in which criminological physiognomy was demonstrated to be fallacious. R. C. Sommerville in 1924 subjected the claims of physiognomy to quantitative tests and discovered little or no relationship between measurable psychological traits and measurable physiognomic characteristics.

H. L. Hollingworth in 1922 summarized experiments conducted under his direction, finding little or no relation between physiognomic measurements and psychological traits. D. G. Paterson in 1930 published an extended critical evaluation of available quantitative studies completed during the preceding 40 years, revealing a consistent trend of negative results. The net result is the classification of physiognomy as pseudo science.

Body build as a subdivision of physiognomy in its broadest meaning has persisted from the time of Hippocrates (450 B.C.) as having diagnostic significance, medically, psychiatrically and psychologically. Verification of the medical significance of differences in body build is found in the work of George Draper in 1924 and in C. M. Jackson's discussion of normal and abnormal human types in *The Measurement of Man* (1930). But the attempt to create a morphological basis for psychiatric diagnosis and classification by E. Kretschmer (1925) did not meet with widespread acceptance in the United States. See D. G. Paterson's evaluation, *Physique and Intellect* (1930), and Anne Anastasi and J. P. Foley, *Differential Psychology*, rev. ed. (1949).

Physiognomic claims are easy to scotch but hard to kill, as is revealed by the constant revival of old beliefs or the creation of new beliefs and systems; witness the elaborate system of somatotypy as developed by W. H. Sheldon in 1940 and 1945. An attitude of suspended judgment was strongly indicated for Sheldon's work.

BIBLIOGRAPHY.—For information on artistic anatomy as applied to physiognomy see the catalogue of 62 authors by Ludwig Choulant, *Geschichte und Bibliographie der anatomischen Abbildung*, etc. (Leipzig, 1852), and the works of the authors enumerated above, especially those of Aristotle, Porta, Cardanus, Corvus and Bulwer. For physiognomy of disease, besides the usual medical handbooks, see Cabuchet, *Essai sur l'expression de la face dans les maladies* (Paris, 1801); P. Mantegazza, *Physiology of Pain* (1893); Polli, *Saggio di fisiognomonia e potognomonia* (1837); and George Draper, *Human Constitution* (Philadelphia, 1924). For ethnological physiognomy, see among older authors Gratarolus, and among moderns the writers cited in the various textbooks on anthropology, especially Schadow, *Physiognomies nationales* (1835), and Park Harrison, *Journal of the Anthropological Institute* (1883). For the physical characteristics of criminals see C. Lombroso, *L'Uomo delinquente* (1897); Ferri, *L'omicidio* (1895); Baer, *Der Verbrecher* (1893); Laurent, *Les Habitudes des prisons* (1890); Havelock Ellis, *The Criminal* (1901); Sir Charles Goring, *The English Convict* (1913); A. Lenz, *Grundriss der Kriminalbiologie* (Vienna, 1927); L. Grimberg, *Emotion and Delinquency* (New York, London, 1928). For psychological and

psychiatric implications see K. Pearson, "Relationship of Intelligence to Size and Shape of Head," *Biometrika*, 5:105-146 (1906); R. C. Sommerville, *Physical, Motor, and Sensory Traits* (1924); E. Kretschmer, *Physique and Character* (New York, 1925); H. L. Hollingsworth, *Judging Human Character* (New York, 1922); D. G. Paterson, *Physique and Intellect* (New York, 1930; London, 1931); W. H. Sheldon, S. S. Stevens and W. B. Tucker, *Varieties of Human Physique* (New York, 1940); W. H. Sheldon and S. S. Stevens, *Varieties of Temperament* (New York, 1942). (A. Mac.; D. G. P.)

PHYSIOLOGICAL PSYCHOLOGY: see **PSYCHOLOGY**.

PHYSIOLOGUS. *Physiologus* (*Naturalist*) was the title given to the early form of a collection of Christian allegories which were widely read in the middle ages. As early as the 2nd century B.C. a *physiologus* seems to have existed. About A.D. 500 it was denounced by that title in a papal decree, but it continued to be popular and developed into the bestiary, being based primarily on the animal world.

As an example of the inaccuracy of the natural history of the *Physiologus*, its description of the "ant-lion" follows: "His father hath the shape of a lion, his mother that of an ant; the father liveth upon flesh, and the mother upon herbs. And these bring forth the ant-lion, a compound of both, and in part like to either, for his fore part is that of a lion, and his hind part like that of an ant. Being thus composed, he is neither able to eat flesh like his father, nor herbs like his mother; therefore he perisheth from inanition"; the moral follows.

(See **BESTIARY**.)

PHYSIOLOGY is that branch of the study of plants and animals (biological science) which concerns itself with the ways in which these living organisms carry out the various processes necessary to life. Among biologists it is common to say that "physiology is the study of function." This is a way of saying that physiologists ask about an organism; "What makes it work?" "What does a heart (or a liver or a kidney) do and how does it do it?" "How does an amoeba move or a muscle lift a weight?" These and a multitude of other questions the physiologist asks and seeks to answer. In a sense a physiologist can be compared with a curious child who, when presented with a toy or a working machine such as a clock, is not content until he has seen all the parts and knows what contribution each makes to the over-all performance.

This article seeks merely to state in some detail what physiology is as a science, to state the problems with which a physiologist is properly concerned, to outline some of the methods by which a physiologist approaches the solution to these problems and to state in general terms the things organisms do and how they do them. No attempt is made to describe in detail the functions of individual organisms, of the organs of which they are made up or of the individual cells which in turn make up the organs. These are described elsewhere. (See **MEDICAL ARTICLES** and **PHYSIOLOGY, ARTICLES ON**.) Some textbooks dealing with physiology are listed in the bibliography at the end of this article. Those listed as elementary books can be read with profit without previous training in biological science.

Scope of Physiology.—Physiologists as a group have as objects of interest the vast variety of living organisms ranging from single-celled organisms such as bacteria, protozoa, algae, etc., through the multicellular animals and plants. Since the things done by the organism as a whole, the roles of individual organs and even the contributions made by cells or parts of cells (e.g., the cell surface, the nucleus, mitochondria, etc.) may be studied, the boundaries of physiology may be said to be virtually limitless. With so many objects and processes for study it is not surprising that specialization has occurred among physiologists and that subfields bearing names indicative of the interest of the workers therein have arisen. Thus there is human physiology, which deals with functions in man, and this may be further subdivided into neurophysiology (functioning of the nervous system), cardiovascular physiology (heart and blood vessels), etc. Plant physiology and other comprehensive major fields have similar subdivisions.

Some physiologists are concerned with similarities and differences between the methods used by various organisms to solve the problems of existence. This branch is known as comparative

physiology. Closely allied to this is a branch which seeks to integrate the findings of all the other branches into one coherent picture. Those having this catholicity of interest call themselves general physiologists. In addition to all the above, virtually every other specialized field in the biological sciences, such as embryology, anatomy and pathology, is concerned with the physiological aspects of the phenomena of interest to it.

The above answers to little more than naming the subdivisions of physiology. What questions and what investigations may a physiologist properly pursue? Let us take human physiology. We are conceived, we are born, we grow, live, love, beget offspring, work for a living, grow old and finally die. We have ideas and desires, converse, write books and lead an intellectual life which includes thinking about our relations to God and our fellow man. All these are things we do, but are they proper subjects for investigation by the physiologist? The answer is, "Not all of them, at least not now." The physiologist must be modest in his assault on the mysteries of nature. As stated before he asks questions such as "How does a muscle lift a weight?" "How does a kidney secrete urine?" "Why does one's heart beat faster following exercise?" Such questions are amenable to experimental investigation in that single, possibly influential factors, such as temperature, magnitude of a weight, speed of lifting, etc., can be varied and rules deduced which permit predictions about what will happen in a given set of circumstances in the future. It may ultimately be possible to predict the most complex manifestations of human behaviour from an integration of a large number of these simpler findings.

Experimental Methods of Physiology.—If a person is presented with a complex thing, how is he to go about ascertaining what it does and how it does it? One way is simply to observe it grossly and see what it does. For example, it may move spontaneously. Alternatively it may move only if kicked, shocked with electricity, heated or otherwise stimulated. If it is desired to know more about how and why it does these things, it will help to know more about the parts which go to make up the machine. Some of these may in turn be complex; for example, the engine or gear box in an automobile.

Ultimately the investigator would like to know what the smallest parts are, what role they play in the substructures and what each of these contributes to functioning of the machine as a whole. He will want to know what the fuel or energy source is for work which is done, what kind of temperatures are attained, what kind of pressures can be exerted, etc. Also he will want to know how the whole machine integrates its activities, how messages are sent by one part to another or influence otherwise exerted.

The gross observational, descriptive phase of the study of the functioning of many (but far from all) living organisms has been carried very far, including description of the major role of individual organs. Thus it is known that in man the heart is a muscular pump which causes the blood to circulate through a closed system of tubes, the blood vessels; the kidneys secrete urine; the stomach digests food; etc. Modern physiologists are more concerned with a detailed understanding of the ways in which these over-all processes are accomplished and controlled, the role of the different kinds of cells which make up the organ and the exact chemical and physical processes which contribute to the final result.

How does the physiologist go about establishing the function of a part of an organism? One obvious method is to remove the part and see what deficiency, if any, the organism suffers as a result of the removal. In some cases removal may be fatal, and the investigator cannot observe the organism long enough to learn much. Less drastically, chemical (*e.g.*, drugs) or physical (*e.g.*, clamping off a blood vessel) means of temporarily handicapping the part may be found. Still less drastically, the investigator may induce a change in the degree of a particular activity and see what organ (or part of an organ) increases or decreases its own activity in parallel with the change. In favourable instances a part may be removed and its role taken over by some mechanical device; for example, a heart may be replaced by a mechanical pump. Alternatively, giving certain chemical substances to an organism may com-

pensate for removal of an organ; *e.g.*, the hormone thyroxine may be taken by mouth to compensate for removal of the thyroid gland. Organs having several functions may require, in compensation for their removal, complex measures. Thus the giving of the hormone insulin can compensate only in part for the removal of the pancreas of an animal. The utilization of sugar may be regulated, but other measures are required to compensate for the loss of substances normally produced by the pancreas which assist in the digestion of food. In summary, much that has been learned and is being learned in physiology depends on observation of the changes which take place when the activities of the organism are disturbed.

To assist him in inducing these changes and in observing them, the physiologist uses instruments for controlling and measuring temperatures, pressures, electrical potentials and currents, acidity or alkalinity, oxygen consumption, etc. To visualize the parts he is studying he may use the unaided eye for gross structures, the ordinary microscope for cells and their parts, or the electron microscope for very small cells and the fine structure of cells. Hardly an instrument is invented for producing, measuring or recording a physical or chemical change which does not find a use in the hands of the physiologist.

Characteristics of Living Organisms.—When we look around us and see the vast variety of things which we are willing to accept as living organisms, the thing which almost invariably impresses us is their diversity of form and activity. A plant has no legs, lungs or liver. An animal has no leaves or roots. Even among those things we call "animal" there are great differences in structure and gross activity. Must there be a separate science of physiology for each kind of living thing? In detail, yes, but if we look at the broad outlines, the kinds of things organisms do, we find surprising similarities which may in a sense be taken as a definition of a living organism. Living organisms are discrete from their environment and differ from it in chemical composition. They are forced to make exchanges of materials with the environment but manage to maintain enough control over the exchange so as to retain their structure and composition. They metabolize; *i.e.*, burn or degrade some materials to obtain energy for growth, activity and repair of the living machinery. They reproduce themselves in kind, co-ordinate the activities of their various parts and manage to adjust to the nature of and changes in their environment. These characteristics are discussed more fully in the following sections. Admitting that not all living organisms at all times have all these characteristics (though exceptions are rare), we shall outline them, for it is within this context that the physiologist works.

Discontinuity From the Environment.—Living organisms are obviously different from the region which surrounds them. That is, they are made up in part of chemical compounds, such as proteins, nucleic acids, etc., which do not normally exist in this surrounding region called the environment. Furthermore the organism consists of a cell or group of cells each of which is surrounded by a membrane or cell surface. Within this cell surface the watery solution called protoplasm usually has a chemical composition quite different from the environment. This is true not only about proteins, fats, carbohydrates, etc., but even about the ions of simple salts. Some of these, such as sodium and chloride ions, though plentiful in the environment may be virtually absent from the cell interiors. Others, such as potassium ions, may be accumulated by the cells so that the concentration inside is much greater (perhaps twentyfold) than that in the environment. The existence of organized structures and the differences in chemical composition between the organism and the environment represent work done by the organism. It may be said that one of the characteristics of a living organism is that it exists as a discontinuity or inhomogeneity in the environment.

Exchanges With the Environment.—Merely existence as an inhomogeneity in the environment is not enough to distinguish a living organism. A lump of coal, a piece of wood or a complex machine has the same attribute. However, such inanimate things, once established, continue to exist with a given allotment of materials. Living organisms, on the other hand, maintain their

structure in spite of changes in the identity of the molecules of which they are made. This requires that the organism exert control over what comes in and what goes out.

The surfaces which cover individual cells, the linings of certain organs (e.g., gut, lung, kidney) and sometimes the external coverings of multicellular organisms are *semipermeable*. This means that they permit some substances to cross them with relatively little difficulty; other materials, usually large molecules, cannot pass the barrier. The semipermeable membranes control qualitatively the kinds of material which pass the barrier. If this were the only control exerted, those materials which could pass would tend to come to equal concentration inside and outside the organism. Only continued production or consumption of a material could maintain a concentration difference. However, there is frequently superimposed on this passive penetration of the membranes an active pumping mechanism which can move materials from a region of low concentration to one of higher concentration. This, in principle, is like pumping water uphill and requires expenditure of energy on the part of the organism.

Man and most multicellular organisms have two environments, an external environment and an internal environment. The air or water that surrounds the organism as a whole and that may penetrate into the lungs and gut constitutes the external environment, and it is with this that exchanges ultimately take place. So far as most of the cells of the body are concerned, however, they are remote from this external environment. They are surrounded by the blood and tissue fluids, and so far as such cells are concerned this is their environment, and they make exchanges with it. This is the internal environment of the organism.

The major places at which exchanges with the external environment occur in the case of man are the lungs, gut and kidney. The skin also participates to some extent. The lungs, gut and kidney have two characteristics in common: (1) they have a very large surface area, and (2) these surfaces are in intimate contact with the finest branches of the blood vessels (capillaries). In the cases of the lung and kidney the large surface is achieved by many successive branchings of a tubular system. In the case of the gut, much of its wall is lined by a multitude of fine, fingerlike protrusions (villi), giving it a somewhat velvetlike surface. The small intestine alone exposes an area of about 10 sq.m. (more than five times the external body surface area), the lung 55 sq.m. of respiratory surface and the kidney about 6 sq.m. In a similar fashion other organisms provide large surfaces for exchange with the external environment; e.g., gills in fishes and other aquatic organisms, leaves and roots in plants. So it may be said that a second characteristic of living organisms is that they are only semi-isolated from the environment and maintain their composition and structure in spite of the necessity for exchanges of material with the environment.

Metabolism.—The tasks of accumulating some materials and ejecting others, as well as such tasks as transporting food and wastes, moving, creating electrical potentials, growing, etc., require energy expenditure. Living organisms obtain this energy from materials called food. Food serves the dual purpose of (1) providing energy and (2) providing materials for growth (increase in mass) and maintenance or repair of the living machinery. Animals obtain energy by oxidizing food materials such as carbohydrates, fats and proteins or by breaking down molecules such as glucose into smaller ones such as lactic acid. These destructive (degradative) processes which provide energy are called catabolism. The building up of more complex molecules from simple ones (synthesis or growth) which requires energy is called anabolism. The sum total of anabolic and catabolic processes is called metabolism.

A few bacteria (known as autotrophic bacteria) obtain their energy for growth by oxidizing simple inorganic materials such as hydrogen, sulphur, iron, ammonia, nitrites, etc. The rest of the living kingdom must be supplied with food directly or indirectly by green plants which obtain from sunlight the energy necessary for synthesis.

With the exception of the green plants which in the light consume carbon dioxide and water while producing oxygen (see

PHOTOSYNTHESIS), organisms (including green plants in the dark) manifest metabolism in one or more of several ways: (1) consumption of oxygen, (2) production of carbon dioxide or other oxidation product (e.g., sulphuric acid from sulphur), (3) production of heat, (4) consumption of food materials, (5) production of incompletely broken-down fragments of food materials. If there is an excess of food over and above that needed for maintenance and activity, then growth or fat deposition will occur. Chemical and physical methods of measuring these changes are used by the physiologist to establish the rate of metabolism.

It is well established that a given quantity of food burned in the body produces the same amount of heat as if it had been burned outside. A piece of bread burned by a chemist using a calorimeter produces the same number of calories as it would if it had been eaten and burned in the body. Further, the amounts of oxygen consumed and carbon dioxide produced are the same in both cases.

One common misconception regarding the results of metabolism of living organisms should be disposed of. This has to do with their anabolic accomplishments. Living organisms synthesize large molecules of bewildering complexity from simple materials. In this they superficially oppose the general tendency of the inanimate world to convert complex things into simple ones, indeed to convert any thing or condition from a high energy state to a lower energy state.

The point which must not be overlooked, however, is that while living organisms are carrying out these marvelous, energy-consuming syntheses, they are simultaneously degrading other food materials to obtain the requisite energy. Indeed, in growth as in other work processes the efficiency with which living organisms capture and use the energy theoretically available from the food-stuffs they degrade is usually less than 25% and may be less than 5%. Even in the animate world it has yet to be demonstrated that something can be got for nothing.

Elucidation of the precise details of the chemical reactions involved in metabolism lies in the province of biochemistry (*q.v.*). The physiologist, however, must keep abreast of biochemical findings and integrate them into the over-all picture of the functioning of living organisms. Fortunately it appears that not only the different tissues of a given organism, but virtually all organisms that have been studied, employ much the same over-all schemes of metabolism. Thus the chain of reactions by which a yeast cell breaks down glucose to two molecules of ethyl alcohol is, except for the final few steps, the same as that used by a muscle cell in man to prepare the fragments of glucose for oxidation. Particular organisms or cell types may be capable of carrying out reactions unique to them—such as production of a hormone, a bacterial toxin or an enzyme; but this usually represents only a small fraction of their total metabolic effort and is of interest only in special connections.

While the biochemist studies the individual intermediary chemical reactions of anabolism and catabolism, frequently isolating single enzyme systems which perform only one chemical step, the physiologist is more likely to study the grosser manifestations of metabolism, such as total oxygen consumed by an organism, the carbon dioxide produced, the amount of heat produced, the weight gained or lost by an individual, the nitrogen excreted, etc. The effect of various activities such as sleeping, sitting at a desk and thinking, walking, doing hard physical labour, etc., on metabolism may be studied as well as disturbances of metabolism caused by diseases or the malfunction of an endocrine gland. An attempt is then made to interpret the findings in terms of known biochemical reactions.

Internal Co-ordination of the Organism.—A living organism consisting of many parts which may be physically remote from each other would not long survive if the activities of these parts were not co-ordinated. The price of specialization is dependence on others for performance of activities given up. The gain, if all goes well, is in terms of increased versatility, efficiency, power and elegance of performance for the organism as a whole. For all to go well there must be communication between parts, some means of delivering goods and messages. This is particularly true when

the demands for material or service vary from time to time. The mechanisms by which living organisms accomplish this internal co-ordination of their parts are three: (1) a transport system, the circulatory system, which brings some materials to individual cells and carries away others, (2) a system of organs, the endocrine system, which sends chemical messengers (hormones) via the circulatory system to the various parts, and (3) a nervous system, which rapidly carries electrical (and, terminally, chemical) messages from one part to another.

Only in the smallest organisms and individual cells are the distances which separate the parts short enough to permit the random movements of molecules to transport materials and to equalize temperatures. Even in small cells (*e.g.*, protozoa, individual plant cells) a sort of internal stirring of the cytoplasm is resorted to, and a cyclic current in the protoplasm (cyclosis) serves as a primitive transport system. Larger organisms speed up the process of transport by means of a circulatory system. In animals this typically consists of a muscular pumping organ, the heart, which forces a fluid through a system of ramifying tubes the terminal branches of which lie in close proximity to the individual body cells. In plants, vascular bundles carry materials between roots, leaves, and other tissues. Typically, in both plants and animals, the tubes of the circulatory system are separated from the body cells by the tissue fluid which surrounds cells. Materials move largely by diffusion from the cells to the tissue fluid to the circulating fluid and vice versa. The tissue fluid is specifically what was called above the internal environment; *i.e.*, the environment of the individual body cells.

Circulatory systems carry materials from regions where they are in large supply to regions where they are to be (1) immediately utilized, (2) stored or (3) eliminated. Thus oxygen may be picked up from lungs, gills or skin in various organisms. Food is picked up from the gut following digestion or from storage depots such as the liver (carbohydrate) or subcutaneous tissue (fat). These are delivered to the tissues. Conversely the wastes of metabolism are picked up from the tissues and delivered to the lung (carbon dioxide) or kidney (urea and various materials) for elimination. Temperature throughout the body is equalized and controlled by the blood's being warmed in rapidly metabolizing tissues and cooled at the body surface or by less rapidly metabolizing tissues.

In addition to food and wastes the circulatory system carries the chemical messengers called hormones throughout the body. These are produced in endocrine glands (also called ductless glands or glands of internal secretion) or, in some cases, by cells located in organs primarily devoted to other tasks. These hormones induce a new state of activity in some other tissue or organ. Depending on the nature of the hormone and on the nature of the receptor tissue, activity may be either stimulated or inhibited. Indeed a single hormone may cause opposite reactions in two different regions. Thus adrenalin causes constriction of the blood vessels of the skin and viscera while causing dilation of the blood vessels in the muscles. Since adrenalin is secreted in times of stress, the net result is to shift blood from tissues where it can be temporarily dispensed with to the tissues which may need an unusually great supply. The organism is prepared for "fight or flight."

Hormones are used for communication in the organism when time, in terms of a fraction of a second, is of no great importance. Thus the growth hormone secreted by the pituitary gland may as well accomplish its work a few hours from now as immediately. Contrast this with the speed required when a person touches a hot stove. Thousandths of a second are important, and, as seen below, the faster-communicating nervous system is utilized. On the other hand, the hormones can induce a long-continued response which, if the nervous system were required to produce it, would call for long-continued, repetitive stimulation.

Finally, with regard to hormonal control of bodily activities, we find a method utilized which has been called push-pull control. By this is meant that one hormone stimulates while another inhibits the activity of a tissue. This principle also is involved in the nervous system. The advantage gained is that of more precise and delicate control of activity. It is the same advantage that

exists in a motorcar equipped with both an accelerator and brakes. Better speed control is obtained than would be possible with either alone.

Control by hormones has been compared with sending letters through the postal system; that is, a message involving a material thing is sent and goes relatively slowly. The nervous system might by similar analogy be compared with a telephone or telegraph system. Messages involving electrical transmission along specifically designed conducting strands are transmitted rapidly from point to specific point. These analogies will not hold up in detail, but they are grossly accurate. While it is true that an electrical impulse travels along a nerve fibre, at the terminus the final stimulation of the cell to be affected is probably accomplished by release of a chemical. However they do it, nerves can carry messages several feet in a few thousandths of a second, whereas (in man) one complete circuit of the blood may require a minute. Thus hormonal messages, even if the hormone were instantaneously secreted, are bound to travel more slowly.

Most of the internal co-ordination in man and the higher vertebrates is accomplished by that part of the nervous system known as the autonomic nervous system. This system is autonomous in the sense that it is not under the control of the will. Indeed we are not conscious of its activities. However, our emotions may affect the autonomic nervous system, causing dilatation or constriction of the blood vessels, acceleration or deceleration of the heart, secretion of hormones, etc. The autonomic system sends both stimulatory and inhibitory nerve fibres to many organs, thus providing for push-pull action and greater delicacy of control.

Homeostasis.—One of the achievements of the internal co-ordination of organisms is the maintenance of a considerable constancy of conditions within the body. This has been called homeostasis (from *homoios*, of the same kind, and *stasis*, to stand; therefore, freely speaking, to stand still). The mechanisms whereby constancy is maintained are called homeostatic mechanisms.

Many conditions in the body are so constant that minor departures from the normal can be used in the diagnosis of disease, at least if they persist. Thus, in man the body temperature, and in the blood the amount of sugar, the slight alkalinity, the concentration of various salts, the number of red or white cells, etc., are constant or vary only within narrow limits. By and large, it is the internal environment which is kept constant. Indirectly the individual body cells are thus helped to have a constant composition and level of activity or, at least, to return quickly to normal if temporarily altered. Those who care to pursue the matter further should keep homeostasis in mind, particularly when reading about respiration, circulation, kidney function, endocrine organs and the nervous system.

Co-ordination With the Environment.—In addition to co-ordinating itself internally, an organism must adjust its activities in such a way as to take into account the nature of and changes in its environment. This involves the ability to sense the nature of the environment and detect changes in it. In some less specialized organisms this ability seems to be simply a general property of the individual cell, although even here there may be localized regions of the cell which are particularly sensitive to given stimuli (*e.g.*, the light-sensitive regions in some protozoa). More specialized organisms have certain cells or groups of cells which are exquisitely sensitive to one or another kind of stimulus (eyes to light, ears to sound, etc.). These are called organs of special sense and along with the nervous system provide for co-ordination with the environment.

The kinds of influences in the environment which serve as signals to an organism may be classified roughly as light, mechanical vibrations, pressure, temperature and chemical constitution of the environment. All the organs sensitive to these environmental factors are of necessity located at or are in direct proximity to the surface of the body. In more highly developed animal organisms many of them are localized in the head region and their nervous connections go directly to the brain. This is particularly true of the organs of sight, hearing, taste and smell. Others, such as the end organs sensitive to touch, heat, cold and pressure, are rather

diffusely distributed over the body surface.

The organs of special sense communicate by means of sensory or afferent nerves with the central nervous system (brain or spinal cord). From the central nervous system motor or efferent nerves carry messages to effector organs such as muscles or glands, which respond by contracting or secreting. What happens in the central nervous system between the time of entry of the sensory nerve impulse and the exit of the motor impulse may be reasonably simple or bafflingly complex. When the spinal cord, and not the brain, is involved, the simplest arrangement is to have the sensory neurone connect directly in the cord with the motor neurone. Such a series—receptor, sensory neurone, motor neurone and effector—constitutes the basic reflex arc. Commonly one or more neurones are interposed between the sensory and motor ones. Such reflex arcs with connections made at the cord level provide for quickly withdrawing a finger which touches a hot stove and other quick reactions. There is no time to think and no thought is necessary.

Beyond the simple reflex, increasing degrees of complexity are found: Transmission of impulses up and down the cord and integrating actions of the brain involving large numbers of neurones occur. For a detailed description of these see BRAIN; NERVE; and SPINAL CORD.

Adaptation and Adaptive Amplification.—Seemingly opposed to homeostasis, discussed above, are the phenomena of adaptation. These consist of all the changes in position, activity and structure which an organism undergoes so that it can better survive. An animal may grow a heavier coat of fur in winter and shed it in the summer. A man in the same circumstances may eat more and become more active, thus producing more heat. Another animal may hibernate, changing the whole level of its metabolism. Of course there are limits to the stress which can be compensated for. Under extreme conditions an organism may be forced to alter its environment (e.g., by building shelters or building a fire) or it may be forced to remove itself to a new and more favourable environment. Adaptations are made not only to external situations but to changes within the organism. If one kidney is lost, the other enlarges so as to do the work of two. Similarly, the heart may enlarge in response to a work load. These *compensatory hypertrophies* are adaptive and their value is obvious. One way of looking at adaptation is to think of it as subserving homeostasis along with the general welfare of the organism. Some structures and activities change in order to maintain others constant.

One of the most distinguishing characteristics of living organisms is their capacity for adaptive amplification. By this is meant their capacity to expend a great deal of energy for an adaptive reaction in response to a small stimulus. Thus a small amount of light falling on the eye or a few sound waves striking the ear of a man may warn him of danger and call for a long-continued response requiring many times the energy put in by the stimulus.

PI, the Greek letter π , used to denote the ratio of the circumference of a circle to its diameter: 3.14159

PIACENZA, in Latin PLACENTIA; a town and episcopal see of Emilia, It., the capital of the province of Piacenza, 42½ mi. S.E. of Milan and 91 mi. N.W. of Bologna by rail. Pop. (1951) 60,114 (province) 299,138. It lies on the Lombard plain, 217 ft. above sea level, near the Po just below the confluence of the Trebia. It is still surrounded by walls with bastions and fosse in a circuit of 4 mi.

The cathedral was erected between 1122 and 1233, in the Lombard Romanesque style; the campanile (1341) is 223 ft. high. The entire edifice was restored after 1898, and the frescoes by Guercino, Lodovico Carracci and Camillo Procaccini seem inappropriate to its severe style. The church of Sant' Antonio, formerly the cathedral, was rebuilt in 1014. S. Francesco is a Gothic edifice begun by the Franciscans in 1278. S. Savino, a Romanesque building of A.D. 903 (rebuilt in 1107 and restored in 1902), contains a mosaic pavement with curious representations, including one of a game of chess. S. Sisto (1499-1511) once contained Raphael's Sistine Madonna, sold in 1754 to Frederick Augustus III of Saxony and replaced by a copy by Pier Antonio Avanzini; and there are also several good intarsias by Bartolomeo da Busseto. The Palazzo Comunale, begun in 1281, is built in marble and brick, with beautiful windows. The Palazzo dei Tribunali and the Palazzo degli Scotti are early Renaissance brick buildings with terra-cotta decorations. The huge Farnese palace was begun after Giacomo da Vignola's designs by Margaret of Austria in 1558 but was never completed; from 1800 it was used as barracks. The town has an automobile factory. It is an important agricultural centre.

Placentia was made a Roman colony in 218 B.C., in which year it afforded protection to the remains of the Roman army after the battle of the Trebia (q.v.). In 207 it withstood a siege by Hasdrubal. Seven years later the Gauls burned it; and in 190 it was recruited with 3,000 families. Later it became an important road centre; the Via Aemilia connected it with Ariminum and the south and was continued across the Po toward Milan, with a branch to Ticinum; the Via Postumia from Cremona to Dertona and Genoa passed through; and Augustus reconstructed the road from Dertona to Vada and into Gallia Narbonensis and gave it the name of Julia Augusta from Placentia onward. The rectangular arrangement of the streets in the centre of the town is Roman.

Piacenza was one of the leading members of the Lombard league. In 1447 it was sacked by Francesco Sforza. Papal forces occupied it in 1512, and Pope Paul III united it with Parma in 1545 to form a hereditary duchy for his son Pierluigi Farnese. The male line of the Farnese (q.v.) family held it till 1731, after which it passed with Parma to the infant Charles. On Charles's becoming king of the Two Sicilies, it passed to the house of Habsburg; it was ceded to Savoy from 1743 to the peace of Aix-la-Chapelle; then it was given with Parma and Guastalla to Charles's brother Philip (1748). (See PARMA.) In 1848 Piacenza was the first town of Lombardy to join Piedmont. In World War II the town suffered 92 air raids between May 1944 and April 1945. The two bridges across the Po were destroyed in the Allied offensive, and 234 houses were totally obliterated; part of the Gothic church of the Carmine Vecchio was destroyed, and G. P. Lomazzo's fresco of the Last Supper in the convent of Sant' Agostino was badly damaged.

PIANOFORTE. The group of keyed stringed musical instruments, among which the pianoforte is latest in order of time, has been invented and step by step developed with the modern art of music. During the 18th century the "organum" arose, an elemen-

tary system of accompaniment to the voice, consisting of fourths and octaves below the melody and moving with it, and the organ (*q.v.*), the earliest keyed instrument, was, in the first instance, the rude embodiment of this idea and convenient means for its expression. About the same time arose a large stringed instrument, the organistrum, the parent of the now obsolete hurdy-gurdy; as the organ needed a blower as well as an organist, so the player of the organistrum required a handle-turner, by whose aid the three strings of the instrument were made to sound simultaneously upon a wheel, and, according to the well-known sculptured relief of St. George de Boscherville, one of the strings was manipulated by means of a row of stoppers or tangents pressed inwards to produce the notes. The other strings were drones, analogous to the drones of the bagpipes, but originally the three strings followed the changing organum.

In the 11th century (the epoch of Guido of Arezzo [*q.v.*], to whom the beginning of musical notation is attributed), the Pythagorean monochord, with its shifting bridge, was used in the singing schools to teach the intervals of the plain-song of the church. The practical necessity, not merely of demonstrating the proportionate relations of the intervals, but also of initiating

pupils into the different gradations of the church tones, had soon after Guido's time brought into use quadruplex monochords, which were constructed with scales so that four lines indicated authentic and the four plagal tones. This arrangement found great acceptance, for Aribio, writing about fifty years after Guido, says that few monochords were to be found without it. Aribio strenuously endeavoured to improve it, and "by the grace of God" invented a monochord measure which, on account of the rapidity of the leaps he could make with it, he named a *caprea* (wild goat). Jean de Muris (*Musica speculativa*, 1323) describes the musical instruments known in his time, but does not mention the clavichord or monochord with keys, which could not have been then invented. Perhaps one of the earliest forms of such an instrument, in which stoppers or tangents had been adopted from the organistrum, is shown in fig. 1, from a wood carving of a vicar choral or organist, preserved in St. Mary's church, Shrewsbury. The latest date to which this figure may be attributed is 1460.

In the Weimar *Wunderbuch*, a MS. dated 1440 with pen and ink miniatures is given a "clavichordium" having 8 short and apparently 16 long keys. The artist has drawn 12 strings in a rectangular case, but no tangents are visible. A keyboard of balanced keys existed in the little portable organ known as the regal, so often represented in old carvings, paintings and stained windows. Vitruvius, *De architectura*, lib. x. cap. xi., translated by Newton, describes a balanced keyboard; but the key apparatus is more particularly shown in *The Pneumatics of Hero of Alexandria*, translated by Bennet Woodcroft (London, 1851).

The name of regal was derived from the rule (*regula*) or graduated scale of keys, and its use was to give the singers in religious processions the note or pitch. The only instrument of this kind known to exist in the United Kingdom is at Blair Atholl, and it bears the very late date of 1630. The Brussels regal may be as modern. (See Victor C. Mahillon, *Catalogue Descriptif* [1880], I. p. 320, p. 454.) We attribute the adaptation of the narrow regal keyboard to what was still called the monochord, but was now a complex of monochords over one resonance board, to the latter half of the 14th century; it was accomplished by the sub-

stitution of tangents (fixed in the ends of the balanced keys) for the movable bridges of the monochord or such stoppers as are shown in the Shrewsbury carving. Thus the monochordium or "payre of monochordis" became the clavichordium or "payre of clavicordis"—pair being applied, in the old sense of a "pair of steps," to a series of degrees. Ed. van der Straeten (*La Musique aux Pays Bas*, i. 278) reproduces a so-called clavichord of the 15th century from a MS. in the public library at Ghent. The treatise is anonymous, but other treatises in the same MS. bear dates 1503 and 1504. In the Weimar *Wunderbuch* is a pen-and-ink sketch of the "clavicimbalum" placed upon a table, in which we recognize the outline of the harpsichord, but on a smaller scale.

The earliest known record of the clavichord occurs in some rules of the minnesingers, dated 1404, preserved at Vienna. (See Ambros, *Geschichte der Musik* [1892], ii. 226.) The monochord is named with it, showing a differentiation of these instruments, and of them from the clavicimbalum—the keyed cymbal, cembalo (Italian), or psaltery. From this we learn that a keyboard had been thus early adapted to that favourite mediaeval stringed instrument, the "cembalo" of Boccaccio, the "sautrie" of Chaucer.

There were two forms of the psaltery: (1) the trapeze, one of the oldest representations of which is to be found in Orcagna's famous Trionfo della Morte in the Campo Santo at Pisa, and another by the same painter in the National Gallery, London; and (2) the contemporary "testa di porco," the pig's head, which was of triangular shape as the name suggests. The trapeze psaltery was strung horizontally, the "istrumento di porco" either horizontally or vertically—the notes, as in the common dulcimer, being in groups of three or four unisons. In these differences of form and stringing we see the cause of the ultimate differentiation of the spinet and harpsichord. The compass of the psalteries was nearly that of Guido's scale; but according to Mersenne (*L'Harmonie universelle* [Paris, 1636], livre iii., p. 107), the lowest interval was a fourth, G to C, which is worthy of notice as anticipating the later "short measure" of the spinet and organ.

The simplicity of the clavichord inclines us to place it, in order of time, before the clavicimbalum or clavicembalo; but we do not know how the sounds of the latter were at first excited. There is an indication as to its early form to be seen in the church of the Certosa near Pavia. In 1472, chromatic keyboards, which imply a considerable advance, were already in use. There is an authentic representation of a chromatic keyboard, painted not later than 1426, in the St. Cecilia panel (now at Berlin) of the famous Adoration of the Lamb by the Van Eycks. The instrument depicted is a positive organ, and it is interesting to notice in this realistic painting that the keys are evidently boxwood, as in the Italian spinets of later date, and that the angel plays a common chord—A with the right hand, F and C with the left. But diatonic

FIG. 2.—DIATONIC CLAVICHORD KEYBOARD (GUIDO'S SCALE) FROM VIRDUNG, BEFORE 1511, SHOWING THE SHORT KEYS B FLAT

organs with eight steps or keys in the octave, which included the B flat and the B natural, as in Guido's scale, were long preserved, for Praetorius speaks of them as still existing nearly two hundred years later. This diatonic keyboard, we learn from Sebastian Virdung (*Musica getutscht und auszgezogen*, Basel, 1511), was the keyboard of the early clavichord. We reproduce his diagram as the only authority we have for the disposition of the one short key.

Virdung's diagram of the chromatic is the same as our own familiar keyboard, and comprises three octaves and a note, from F below the bass stave to G above the treble. But Virdung tells

us that even then clavichords were made longer than four octaves by repetition of the same order of keys. The introduction of the chromatic order he attributes to the study of Boetius, and the consequent endeavour to restore the three musical *genera* of the Greeks—the diatonic, chromatic and enharmonic. But the last-named was not attained until equal temperament tuning was developed by J. S. Bach. Virdung gives woodcuts of the clavi-

was now able to produce, in 1722, *Das wohltemperirte Clavier*, his famous collection of preludes and fugues in all the twenty-four major and minor scales for a clavichord which was tuned to what is now known as "equal temperament."

An example of a 17th century clavichord, here called manicordo (as French *manicorde*, from monochord), is illustrated in fig. 4. The lowest octave is here already "bundfrei" or fret-free. The strings are no longer of equal length, and there are three bridges, divisions of the one bridge, in different positions on the sound-

board. Mersenne's "manicorde" (*Harmonie Universelle*, Paris, 1636, p. 115), shown in an engraving in that work, has the strings still nearly of equal length, but the sound-board bridge is divided into five. The fretted clavichords made in Germany in the last years of the 17th century have the curved sound-board bridge, like a spinet. In the clavichord the tangents always formed the second bridge, deciding the pitch, besides acting as the sound exciter (fig. 5). The common damper to all the strings was a "list" of cloth, interwoven behind the tangents. As the tangents

FIG. 5.—CLAVICHORD TANGENT Showing position when front of keyboard is depressed; the tangent rises into contact with the strings and forms the end-point of the speaking length. The back string is kept from vibrating by means of the "Listing" cloth

quitted the strings the cloth immediately stopped all vibration. As regards compass Handel's clavichord now in the museum at Maidstone (an Italian instrument dated 1726, and not fretted), has a compass of $3\frac{1}{2}$ octaves (F to A).

The clavichord must have gone out of favour in Great Britain and the Netherlands early in the 16th century—the more brilliant and elegant spinet being preferred to it. Like the other keyboard instruments it had no German name, and can hardly have been of German origin, but it remained longest in use in Germany—until even the beginning of the 19th century.

The next instrument described by Virdung is the virginal (*virginalis*, proper for a girl), a parallelogram in shape, having the same projecting keyboard and compass of keys as the clavichordium. Here we trace derivation from the psalter, in that the sound-board covers the entire inner surface of the instrument

FIG. 6.—VIRDUNG'S CLAVICIMBALUM (SPINET), 1511; REVERSED FACSIMILE WOODCUT

FIG. 3.—VIRDUNG'S CLAVICHORDIUM (1511); FACSIMILE WOODCUT, REVERSED TO CORRECT THE KEYBOARD

chordium, the virginal, the clavicimbalum and the clavictherium. We reproduce three of them (figs. 3, 6 and 8), omitting the virginal as obviously incorrect. Writers on musical instruments have continually repeated these drawings without discerning that in the printing they are reversed, which puts the keyboards entirely wrong, and that in Luscinius's Latin translation of Virdung (*Musurgia, sive praxis musicae*, Strasbourg, 1536), which has been hitherto chiefly followed, two of the engravings, the clavicimbalum and the clavictherium, are transposed, another cause of error.

Still commonly known as monochord, Virdung's clavichord was really a box of monochords, all the strings being of the same length. We observe in this drawing (fig. 3) the short sound-board, which always remained a peculiarity of the clavichord, and the straight sound-board bridge—necessarily so when all the strings were of one length. To gain an angle of incidence for the tangents against the strings the keys were splayed, an expedient further rendered necessary by the "fretting"—three tangents being placed to give three different notes from each single group of strings tuned in unison. In the drawing the strings are merely indicated. The German for fret is *Bund*, and such a clavichord, in that language, is known as a "gebundenes Clavichord" both fret (to

FIG. 4.—MANICORDO (CLAVICHORD) D'ELEONORA DI MONTALVO (1659); KRAUS MUSEUM, FLORENCE

rub) and *Bund* (from *binden*, to bind) having been taken over from the lute or viol. The French and Italians employ "touche" and "tasto" (touch). Praetorius who wrote a hundred years later than Virdung, says two, three and four tangents were thus employed in stopping.

Clavichords were made with double fretting up to about the year 1700—that is to say, to the epoch of J. S. Bach, who, taking advantage of its abolition and the consequent use of independent pairs of strings for each note, was enabled to tune in all keys equally, which had been impossible so long as the fretting was maintained. The modern scales having become established, Bach

and the disposition of the strings is triangular. The virginal in Virdung's drawing has an impossible position with reference to the keyboard, which renders its reproduction as an illustration useless. But in the next drawing, the clavicimbalum, this is rectified, and the drawing, reversed on account of the keyboard, can be accepted as roughly representing the instrument so called (fig. 6). There would be no difference between the clavicimbalum and the virginal were it not for a peculiarity of keyboard compass, which emphatically refers itself to the Italian "spinetta," a name

bought his "Espinette" from Charles Haward for £5, July 13, 1664. Thomas Hitchcock (for whom there are dates 1664 and 1703 written on keys and jacks of spinets bearing Edward Blunt's name and having divided bass sharps) made a great advance in constructing spinets, giving them the wide compass of five octaves, from G to G, with very fine keyboards in which the sharps were inlaid with a slip of the ivory or ebony, as the case might be, of the naturals.

We have now to ask what was the difference between Scaliger's harpichordum and his clavicymbal. Galilei, the father of the astronomer of that name (*Dialogo della musica antica e moderna*, Florence, 1581), says that the harpichord was so named from having resembled an "arpa giacente," a prostrate or "couched" harp, proving that the clavicymbal was at first the trapeze-shaped spinet; and we should therefore differentiate harpichord and clavicymbal as derived from the harp and psalttery respectively.

The Latin name "clavicymbalum," having early been replaced by spinet and virginal, was in Italy and France bestowed upon the long harpichord, and was continued as clavicembalo and clavecin. Much later, after the restoration of the Stuarts, "harpichord" was accepted and naturalized in England as harpsichord, which we will define as the long instrument with quills, shaped like a modern grand piano. We can point out no long instrument of this kind so old as the Roman cembalo at South Kensington. The outer case is of finely tooled leather. It has a compass of nearly four octaves, E to D, and the natural keys are of boxwood.

The startling "piano e forte" of 1598, brought to light from the records of the house of D'Este by Count Valdrighi of Modena (see Van der Straeten, vi, 122), we are disposed to regard, not as an anticipation of Cristofori's subsequent invention of the pianoforte, but as an ordinary cembalo with power to shift by a stop, from two unisons (forte) to one string (piano), at that time a Flemish practice, and most likely brought to Italy by one of the Flemish musicians who founded the Italian school of composition.

About the year 1600, when accompaniment was invented for monody, large cembalos were made for the orchestras to bring out the bass part, the performer standing to play. Such an instrument was called "archicembalo," a name also applied to a large cembalo, made by Vito Trasuntino, a Venetian, in 1606, intended by thirty-one keys in each of its four octaves, to restore the three genera of the ancient Greeks.

Double keyboards and stops in the long cembalo or harpsichord came into use in the Netherlands early in the 16th century. We find them imported into England. The following citations, quoted by Rimbault in his *History of the Pianoforte*, are from the privy purse expenses of King Henry VIII.

"1530 (April). Item the vii dayes paid to William Lewes for ii payer of virginals in one coffer with iiiii stoppes brought to Grenewiche iii. li. And for ii payer of virginals in one coffer brought to the More other iii. li."

Now the second instrument may be explained ("virginals" meaning any quilled instrument) as a double spinet, like that at Nuremberg by Martin van der Beest, the octave division being movable. But the first cannot be so explained; the four stops can only belong to a harpsichord, and the two pair instrument to a double-manual. Again from the inventory after the king's death (see Brit. Mus. Harl. MS. 1419) fol. 247—

"Two fair pair of new long Virginals made harp-fashion of Cipres, with keys of ivory, having the King's Arms crowned and supported by his Grace's beasts within a garter gilt, standing over the keys."

This is probably another double keyboard harpsichord. We read

FIG. 10.—CRISTOFORI'S PIANO E FORTE (1726); KRAUS MUSEUM, FLORENCE

in an inventory of the furniture of Warwick Castle, 1584, "a faire paire of double virginals," and in the Hengrave inventory, 1603, "one great payre of double virginals." Hans Ruckers, the great claviselng maker of Antwerp, lived too late to have invented the double keyboard and stops, evident adaptations from the organ, and the octave string was already in use when he began his work. Until the last harpsichord was made by Joseph Kirkman, in 1798, scarcely an instrument of the kind was constructed, except in Italy, without the octaves. The harpsichord as known throughout the 18th century, with "piano" upper and "forte" lower keyboard, was the invention of Hans Ruckers's grandson, Jean Ruckers's nephew, Jan Couchet, about 1640. Before that time the double keyboards in Flemish harpsichords were merely a transposing expedient, to change the pitch a fourth, from plagal to authentic and vice versa, while using the same groups of keys.

After the Antwerp make declined, London became pre-eminent for harpsichords—the representative makers being Jacob Kirckmann and Burckhard Tschudi, pupils of a Flemish master, one Tabel, who had settled in London, and whose business Kirckmann continued through marriage with Tabel's widow. Tschudi was of a noble Swiss family belonging to the canton of Glarus. According to the custom with foreign names obtaining at that time, by which Haendel became Handel, and Schmidt Smith, Kirckmann dropped his final *n* and Tschudi became Shudi, but he resumed the full spelling in the facies of the splendid harpsichords he made in 1766 for Frederick the Great, which are still preserved at Potsdam. By these great makers the harpsichord became a larger, heavier-strung and more powerful instrument, and fancy stops were added to vary the tone effects. To the three shifting registers of jacks were added the "lute," the charm of which was due to the favouring of high harmonics by plucking the strings close to the bridge, and the "harp," a muting effect produced by impeding the vibration of the strings by contact of small pieces of buff leather. Two pedals were also used, the left-hand one a combination of a unison and lute.

The right-hand pedal was to raise a hinged portion of the top or cover and thus gain some power of "swell" or crescendo, an invention of Roger Plenius, to whom also the harp stop may be rightly attributed. The first idea of pedals for the harpsichord to act as stops appears to have been John Hayward's (?Haward) as early as 1676, as we learn from Mace's *Music's Monument*, p. 235. The French makers preferred a kind of knee-pedal arrangement, known as the "genouillère," and sometimes a more complete muting by one long strip of buff leather, the "sourdine." As an improvement upon Plenius's clumsy swell, Shudi in 1769 patented the Venetian swell, a framing of louvres, like a Venetian blind, which opened by the movement of the pedal, and becoming in England a favourite addition to harpsichords, was early transferred to the organ, replacing the rude "nag's-head" swell.

To keep his collection of musical instruments in playing order Prince Ferdinand dei Medici engaged a Paduan harpsichord maker, Bartolommeo Cristofori, the man of genius who invented and produced the pianoforte. We fortunately possess the record of this invention in a literary form from a well-known writer, the Marchese Scipione Maffei; his description appeared in the *Giornale dei letterati d'Italia*, a publication conducted by Apostolo Zeno. The date of Maffei's paper was 1711. Rimbault reproduced it, with a technically imperfect translation, in his *History of the Pianoforte*. We learn from it that in 1709 Cristofori had completed four "gravicembali col piano e forte"—keyed-psalteries with soft and loud—three of them being of the long or usual harpsichord form. The sketch of his action in Maffei's essay shows an incomplete stage in the invention, although the kernel of it—the principle of escapement or the controlled rebound of the hammer—is already there. He obtains it by a centred lever (*linguetta mobile*) or hopper, working, when the key is depressed by the touch, in a small projection from the centred hammer-butt. The return, governed by a spring, must have been uncertain and incapable of further regulating than could be obtained by modifying the strength of the spring. Moreover, the hammer had each time to be raised the entire distance of its fall. There are, however, two pianofortes by Cristofori, dated respectively 1720 and

1726, which show a much improved construction, for the whole of an essential piano movement is there. The earlier instrument (now in the Metropolitan Museum, New York) has undergone considerable restoration, but the 1726 one, which is in the Kraus Museum at Florence, retains the original leather hammer-heads. Both instruments possess alike a contrivance for determining the radius of the hopper, and both have been unexpectedly found to have

FIG. 11.—SILBERMANN FORTE PIANO (1746), STADTSCHLOSS, POTSDAM

the "check" (Ital. *paramartello*), which regulates the fall of the hammer according to the strength of the blow which has impelled it to the strings.

Thicker stringing, to withstand even Cristofori's light hammers, demanded in its turn a stronger framing than the harpsichord had needed. Accordingly to make his structure firm Cristofori considerably increased the strength of the block which holds the tuning-pins, and as he could not do so without materially adding to its thickness, he adopted the bold expedient of inverting it; driving his wrest-pins, harp-fashion, through it, so that tuning was affected at their upper, while the wires were attached to their lower, ends. Then, to guarantee the security of the case, he ran an independent string-block round it of stouter wood than had been used in harpsichords, in which block the hitch-pins were driven to hold the farther ends of the strings, which were spaced at equal distances (unlike the harpsichord), the dampers lying between the pairs of unisons.

Cristofori died in 1731. He had pupils, but did not found a school of Italian pianoforte-making. The 1711 essay of Scipione Maffei was translated into German, in 1725, by König, the court poet at Dresden, and friend of Gottfried Silbermann, the renowned organ builder and harpsichord and clavichord maker (see Dr. Oscar Paul's *Geschichte des Claviers*, Leipzig, 1868). Incited by this publication, and perhaps by having seen in Dresden one of Cristofori's pianofortes, Silbermann appears to have taken up the new instrument, and in 1726 to have manufactured two, which J. S. Bach, according to his pupil Agricola, pronounced failures. The trebles were too weak; the touch was too heavy. There has long been another version to this story, viz., that Silbermann borrowed the idea of his action from a very simple model contrived by a young musician named Schroeter, who had left it at the electoral court in 1721, and, quitting Saxony to travel, had not afterwards claimed it.

Whatever Silbermann's first experiments were based upon, he ultimately adopted Cristofori's pianoforte without further alteration than the compass and colour of the keys and the style of joinery of the case. In the Silbermann grand pianofortes at Potsdam, known to have been Frederick the Great's, and to have been acquired by that monarch

prior to J. S. Bach's visit to him in 1747, we find the Cristofori framing, stringing, inverted wrest-plank and action complete. Fig. 11 represents the instrument on which J. S. Bach played in the Stadtschloss, Potsdam.

It has been repeatedly stated in Germany that Frederici, of Gera in Saxony, an organ builder and musical instrument maker, invented the square or table-shaped piano, the "fort bien," as he is said to have called it, about 1758-60. No square piano by this maker is forthcoming, though an "upright grand" piano, made by Domenico del Mela in 1739, with an action adapted from Cristofori's has been discovered by Signor Ponsicchi of Florence. Victor

FIG. 13.—SCHROETER'S MODEL FOR AN ACTION (1721); SHOWING THE KEY READY TO LIFT THE HOPPER, AND MAKE IT STRIKE THE HAMMER SHANK

Mahillon of Brussels, however, acquired a Frederici "upright grand" piano, dated 1745. In Frederici's upright grand action (fig. 12) we have not to do with the ideas of either Cristofori or Schroeter; the movement is practically identical with the hammer action of a German clock, and has its counterpart in a piano at Nuremberg; a fact which needs further elucidation. We note here the earliest example of the leather hinge, afterwards so common in piano actions. An attempted combination of harpsichord and pianoforte appears very early. The English poet Mason, the friend of Gray, bought such an instrument at Hamburg in 1755, with "the cleverest mechanism imaginable."

It was only under date of 1763 that Schroeter published for the first time a diagram of his proposed invention, designed more than forty years before. It appeared in Marburg's *Kritische Briefe* (Berlin, 1764). Now, immediately after, Johann Zumpe, a German in London, who had been one of Shudi's workmen introduced (there is some tradition that Mason had to do with the invention of it) a "square" piano, which was destined to become the most popular domestic instrument. Zumpe was in fact not the inventor of the square piano, which appears to have been well known in Germany before his date, a discovery made by Mr. George Rose. In Paul de Wit's Musical Instrument Museum—formerly in Leipzig, afterwards transferred to Cologne—there is a small square piano by Hildebrandt 27 in. long 10 in. wide and 4½ in. high, having a contracted keyboard of 3 octaves and 2 notes. The action of this small instrument is practically identical in every

detail with that of the square pianofortes made much later by Zumpe (Paul de Wit, *Katalog des musikhistorischen Museums*, Leipzig, 1903. No. 55, illustration, p. 38). Inside is inscribed: "Friedrich Hildebrandt, Instrumentenmacher in Leipzig, Quer-gasse," with four figures almost illegible. Paul de Wit refers the instrument to the middle of the 18th century. It has all the

appearance of being a reduced copy of a well-established type, differing very little from the later models.

Burney tells us all about Zumpe; and his instruments still existing would fix the date of the first at about 1765. Fétis narrates, however, that he began the study of the piano on a square piano made by Zumpe in 1762. In this simple action (fig. 14) we have the nearest approach to a realization of Schroeter's idea. It will be noted that Schroeter's damper (fig. 13) would stop all vibration at once. This defect is met by Zumpe's "mopstick" damper.

Another piano action had, however, come into use about that time or even earlier in Germany. The discovery of it in the

Viennese instrument, famous for its lightness of touch.

We will quit the early German piano with an illustration (fig. 17) of a square piano action in an instrument made by Johann Gottlob Wagner of Dresden in 1783, and embodying the Cristofori principle rather than the Viennese.

Burney, who lived through the period of the displacement of the harpsichord by the pianoforte, is the only authority to whom

FIG. 15.—EARLIEST KNOWN PIANO ACTION ON THE GERMAN PRINCIPLE OF ESCAPEMENT, WHEREBY THE PIVOT RISES WITH THE KEY AND THROWS THE BUTT AGAINST A FIRM RESISTANCE

simplest form is to be attributed to V. C. Mahillon, who found it in a square piano belonging to Henri Gosselin, painter of Brussels (fig. 19). The principle of this action is that which was later perfected by the addition of a good escapement by Stein of Augsburg, and was again later experimented upon by Sebastian Erard. Its origin is perhaps due to the contrivance of a piano action that should suit the shallow clavichord and permit of its transformation into a square piano. It will be observed that the hammer is, as compared with other actions, reversed, and its pivot rises with the key, necessitating a fixed rail against which the hammer butt strikes. It was Stein's merit to graft the hopper principle upon this simple action; and Mozart's approbation of the invention, when he met with it at Augsburg in 1777, is expressed in a well-known letter addressed to his mother. No more "blocking" of the hammer, destroying all vibration, was henceforth to vex his mind. He had found the instrument that for the rest of his short life replaced the harpsichord. V. C. Mahillon secured for his museum the only Johann Andreas Stein piano which is known to remain. It is from Augsburg, dated 1780, and has Stein's escapement action (fig. 16), two unisons, and the knee pedal.

Mozart's own grand piano, preserved at Salzburg, and the two grand pianos (the latest dated 1790) by Huhn of Berlin, preserved

FIG. 17.—GERMAN SQUARE ACTION (1783); ESCAPEMENT IS EFFECTED AT THE POINT WHERE THE HOPPER FALLS INTO THE NOTCH. PIANO BY WAGNER, DRESDEN

we can refer as to the introduction of the latter instrument into England. He tells us without giving the exact date that the first hammer harpsichord that came to England was made by an English monk at Rome, a Father Wood, for an English gentleman, Samuel Crisp of Chesington; the tone of this instrument was superior to that produced by quills, with the advantage of *piano* and *forte* expression so that, although the touch and mechanism were imperfect, yet in a slow movement like the "Dead March" in *Saul* it excited wonder and delight. Fulke Greville afterwards bought this instrument for 100 guineas, and it remained unique in England for several years, until Plenius, the inventor of the lyrichord, made a pianoforte in imitation of it. In this instrument the touch was better, but the tone was inferior. Plenius produced his lyrichord, a *sostenente* harpsichord, in 1745, and Mason imported a pianoforte ten years later. Burney further tells us that the arrival in London of J. C. Bach in 1759 was the motive for several of the second-rate harpsichord makers trying to make pianofortes, but with no particular success. Of these Americus Backers (d. 1776), said to be a Dutchman, appears to have gained the first place. He was afterwards the inventor of the so-called English action, based upon Cristofori's, and may have made the instrument referred to in an old play-bill of Covent Garden in Messrs. Broadwoods' possession, dated May 16, 1767, which has the following announcement:—

"End of Act 1. Miss Brickler will sing a favourite song from *Judith*, accompanied by Mr. Dibdin on a new instrument call'd Piano Forte."

Backers's "Original Forte Piano" was played at the Thatched House in St. James's Street, London, in 1773. Ponsicchi has found a Backers grand piano at Pistoria, dated that year.

The escapement lever is suggested by Cristofori's first action, to which Backers added a contrivance for regulating it by means of a button and screw (see fig. 18). The check is from Cristofori's second action. John Broadwood and Robert Stodart were friends, Stodart having been Broadwood's pupil; and they were the assistants of Backers in the installation of his invention. On his deathbed he commended it to Broadwood's care, but Stodart appears to have been the first to advance it—Broadwood being probably held back by his partnership with his brother-in-law, the son of Shudi, in the harpsichord business. (The elder Shudi had died in 1773.) Stodart soon made a considerable reputation with his "grand" pianofortes, a designation he was the first to give them. In Stodart's grand piano we first find an adaptation from the lyrichord of Plenius, of steel arches between the wrest-plank and belly-rail, bridging the gap up which the hammers rise. These are not found in any contemporary German instruments, but may have been part of Backers's. Zumpe's small square piano had met with great success; he was soon enabled to retire, and his imitators, who were legion, continued his model with its hand stops for the dampers and sourdine, with little change but that

FIG. 16.—STEIN'S ACTION AFTERWARDS CALLED VIENNESE (1780)
The pivot of the hammer rises with the key and the blow is caused by the end of the hammer coming into contact with the escapement

at Berlin and Charlottenburg, follow Stein in all particulars. These instruments have three unisons upwards, and the muting movement known as *celeste*, which no doubt Stein had also. The wrest-plank is not inverted; nor is there any imitation of Cristofori. Stein's instrument was accepted as a model in Berlin as well as Vienna, to which city his business was transferred in 1794 by his daughter Nanette, known as an accomplished pianist and friend of Beethoven, who at that time used Stein's pianos. Streicher, a pianist, who married Nanette, further improved the

which straightened the keys from the divergences inherited from the clavichord.

John Broadwood took this domestic instrument in hand to improve it, and in the year 1780 succeeded in entirely reconstructing it. He transferred the wrest-plank and pins from the right-hand side, as in the clavichord, to the back of the case, an

FIG. 18.—GRAND PIANO ACTION (1776). THE "ENGLISH" ACTION OF AMERICUS BACKERS

The button screw throws the jack out of the notch in the butt after making the blow; improved by Messrs. Collard (1835), who reversed the lever and hammer butt

improvement universally adopted after his patent, No. 1379 of 1783, expired. In this patent we first find the soft and sustaining pedals, since universally accepted, but at first in grand pianofortes only. John Geib patented (No. 1571 of 1786) the hopper with two separate escapements, one of which was soon adopted in the "grasshopper" of the square piano, it is believed by Geib himself;

FIG. 19.—BROADWOOD'S GRAND PIANO ACTION (1884), ENGLISH DIRECT MECHANISM

The hopper is thrown from the notch in the butt, by the slanting blow given by the set-off button when the hopper rises

and Petzold, a Paris maker, appears to have taken later to the escapement effected upon the key.

To return to John Broadwood—having launched his reconstructed square piano, he next turned his attention to the grand piano to continue the improvement of it from the point where Backers had left it. He called in the aid of professed men of science—Tiberius Cavallo, who in 1788 published his calculations of the tension, and Dr. Gray, of the British Museum. The problem

was solved by dividing the sound-board bridge, the lower half of which was advanced to carry the bass strings, which were still of brass. Even the first attempts to equalize the tension and improve the striking-place were successful in improving the tone greatly. To please Dussek, Broadwood in 1791 carried his five-octave, F to F, keyboard, by adding keys upwards, to five and a half octaves, F to C. In 1794 the additional bass half octave to C, which Shudi had first introduced in his double harpsichords, was given to the piano.

The first square piano made in France is said to have been constructed in 1776 by Sebastian Erard, a young Alsatian. In 1786 he came to England and founded the London manufactory of harps and pianofortes bearing his name. Erard took out his first patent for a "repetition" action in 1808. He did not, however, succeed in producing his famous repetition or double escapement action until 1821; it was then patented by his nephew Pierre Er-

FIG. 20.—COLLARD'S GRAND PIANO ACTION (1884); ENGLISH ACTION, WITH REVERSED HOPPER AND CONTRIVANCE FOR REPETITION ADDED, OPERATING UNDER THE BUTT

ard. When the patent expired in England in 1835 it had proved a loss from the difficulties of carrying out the invention. This induced the House of Lords to grant an extension of the patent.

Erard invented in 1808 an upward bearing to the wrest-plank bridge, by means of agraffes or studs of metal, through holes in which the strings are made to pass, bearing against the upper side. A long brass bridge on this principle was introduced by William Stodart in 1822. A pressure-bar bearing of later introduction is claimed for the French maker, Bord.

The first to see the importance of iron combined with wood (ultimately almost supplanting it) in pianoforte framing was a native of England and a civil engineer by profession, John Isaac Hawkins, known as the inventor of the ever-pointed pencil. He was living at Philadelphia, U.S.A., when he invented and first produced the familiar upright pianoforte—"portable grand" as he then called it. He patented it in America, his father, Isaac Hawkins, taking out the patent for him in England in the same year, 1800.

There had been upright grand pianos as well as upright harpsichords, the horizontal instrument being turned up upon its wider end and a keyboard and action adapted to it. William Southwell, an Irish piano-maker, had in 1798 tried a similar experiment with a square piano, to be repeated in later years by W. F. Collard of London; but Hawkins was the first to make a piano with the strings descending to the floor, the keyboard being raised, and this, although at the moment the chief, was not his only merit. He anticipated nearly every discovery that has since been introduced as novel. His instrument is in a complete iron frame, independent of the case; and in this frame, strengthened by a system of iron resistance rods combined with an iron upper bridge, his sound-board is entirely suspended. An apparatus for tuning by mechanical screws regulates the tension of the strings, which are of equal length throughout. The action, in metal supports, anticipates Wornum's in the checking, and still later ideas in a contrivance for repetition. Southwell appears to have been one of the first to profit by Hawkins's ideas by bringing out the tall cabinet pianoforte, with hinged sticker action, in 1807. All that he could, however, patent in it was the simple damper action, turning on a pivot to relieve the dampers from the strings. The next

steps for producing the short or cottage upright piano were taken by Robert Wornum, who in 1811 produced a diagonally, and in 1813 a vertically, strung instrument. Wornum's improved crank action (fig. 23) was not complete until 1826, when it was patented for a cabinet piano; but it was not really introduced until three years later, when Wornum applied it to his little "piccolo." The principle of this centred lever check action was introduced

FIG. 21.—ERARD'S DOUBLE ESCAPEMENT ACTION (1821)

The escapement of repetition is effected by a spring pressing the hinged lever upwards, to allow the hopper which delivers the blow to return into position, before the key has risen again

into Paris by Pleyel and Pape, and thence into Germany and America. (Pleyel exhibited a small upright piano in Paris in 1827, but Pierre Erard did not turn his attention to upright pianos until 1831.)

Early in the 19th century William Allen, a young tuner in the employ of the Stodarts, devised a metal system of framing intended primarily for compensation, but soon to become, in other hands, a framing for resistance. His idea was to meet the divergence in tuning caused in brass and iron strings by atmospheric changes by compensating tubes and plates of the same metals, guaranteeing their stability by a cross batoning of stout wooden bars and a metal bar across the wrest-plank. Allen consulted Stodart's foreman, Thom; and Allen and Thom patented the invention in January 1820. The firm of Stodart at once acquired the patent.

We now arrive at an important epoch in pianoforte construction—the abolition of the wooden construction in favour of a combined construction of iron and wood, the former material gradually asserting pre-eminence. Allen's design is shown in fig. 24. The long bars are really tubes fixed at one end only; those

FIG. 22.—STEINWAY'S GRAND PIANO ACTION (1884)

The double escapement as in Erard's (fig. 21) but with shortened balance and usual check. The hopper escapes from under the roller owing to the ball-crank lever coming into contact with the set-off button

of iron lie over the iron or steel wire, while those of brass lie over the brass wire, the metal plates to which they are attached being in the same correspondence. At once a great advance was made in the possibility of using heavier strings without danger to the durability of the case and frame. In 1821, a fixed iron string-plate, the invention of one of Broadwood's workmen, Samuel Hervé, was applied to one of the square pianos of that firm. The great advantage in the fixed plate was a more even

resistance to the tension of the strings and the reduction of their length behind the bridge. Long iron resistance bars were experimented on as substitutes for the wooden bracing by Joseph Smith in 1798; but to James Broadwood belongs the credit of trying them first above the sound-board in the treble part of the scale in 1808, and again in 1818; he did not succeed, however, in fixing them properly. Sebastian and Pierre Erard seem to have been first in the field in 1823 with a complete system of nine resistance

FIG. 23.—WORNUM'S UPRIGHT ACTION (1826), ORIGINAL OF THE NOW UNIVERSAL ACTION IN UPRIGHT PIANOS

The Hopper in its ascent drove the hammer forward at the same time contacting the rail which threw the upper end of the hopper out of the notch forming what is known as the escapement. Meanwhile the damper-head is raised by the wire, and the felt is taken from the string

grand pianoforte to depend practically upon iron, in which, to avoid the conspicuous inequalities caused by the breaking of the scale with resistance bars, there should be no bar parallel to the strings except a bass bar, while another flanged resistance bar, as an entirely novel feature, crossed over the strings from the bass corner of the wrest-plank to a point upon the string-plate where the greatest accumulation of tension strain was found. After the Great Exhibition of 1851 he employed an ordinary straight bar in the middle of his concert grand scale, his smaller grands having frequently two such as well as the long bass bar. After 1862 he covered his wrest-plank with a thick plate of iron into which the tuning pins screw as well as into the wood beneath, thus avoiding the crushing of the wood by the constant pressure of the pin across the pull of the string.

The introduction of iron into pianoforte structure was differently and independently effected in America, the fundamental idea there being to use a single casting for the metal plate and bars, instead of forging or casting them in separate pieces. Alphaeus Babcock was the pioneer of this kind of metal construction. He also cast an iron ring for a square piano in 1825, which, although not a success, gave the clue to a single casting resistance framing, successfully accomplished by Conrad Meyer, in Philadelphia, in 1833, in a square piano which still exists, and was shown in the Paris Exhibition of 1878. Meyer's idea was improved upon by Jonas Chickering (1797-1853) of Boston, who applied it to the grand piano as well as to the square, since which time this prin-

bars from treble to bass; with a simple mode of fastening them through the sound-board to the wooden beams beneath. James Broadwood, by his patent of 1827, claimed the combination of string-plate and resistance bars, which was clearly the completion of the wood and metal instrument, differing from Allen's in the resistance being fixed. Broadwood left the bass bars out, but added a fourth bar in the middle to the three in the treble he had previously used. But the weight of the stringing was always increasing, and a heavy close copper covering of the bass strings had become general. The resistance bars were increased to five, six, seven, eight and, as we have seen, even nine, according to the ideas of the different English and French makers who used them in their pursuit of stability.

A method of fastening the strings on the string-plate depending upon friction, and thus dispensing with "eyes," was a contribution of the Collards, who had retained James Stewart, a man of considerable inventive power, who had been in America with Chickering. This invention was introduced in 1827. Between 1847 and 1849 Mr. Henry Fowler Broadwood, grandson of John Broadwood, invented a

ciple has been universally adopted.

We have now to consider over- or cross-stringing, by which the bass division of the strings is made to cross over the tenor part of the scale—the object being in the first instance to get longer bass strings than are attainable in a parallel scale, and in the next to open out the scale and extend the area of bridge pressure on the sound-board. In the 18th century clavichords were sometimes

overstrung in the lowest octave to get a clearer tone in that very indistinct part of the instrument (strings tuned an octave higher being employed). The first suggestion for the overstringing in the piano was made by the celebrated flute-player and inventor Theobald Boehm, who carried it beyond theory in London, in 1831, by employing a small firm located in Cheapside, Gerock & Wolf, to make some overstrung pianos for him. Boehm expected to gain in tone; Pape, an ingenious mechanic in Paris, tried a like experiment to gain economy in dimensions, his notion being to supply the best piano possible with the least outlay of means. Tomkinson in London continued Pape's model, but neither Boehm's nor Pape's took permanent root. The Great Exhibition of 1851 contained a grand piano, made by Lichtenthal of St. Petersburg, overstrung in order to gain symmetry by two angle sides to the case. It was regarded as a curiosity only. Later, in 1855, Henry Engelhard Steinway (originally Steinweg; 1797–1871), who had emigrated from Brunswick to New York in 1849, and had established the firm of Steinway & Sons in 1853 in that city, effected the combination of an overstrung scale with the American iron frame, which exhibited in grand and square instruments shown in London in the International Exhibition of 1862, excited the attention of European pianoforte makers, leading to important results.

It would be inaccurate to say that no outstanding developments have taken place in pianoforte construction during the last fifty years, but few new principles have been discovered, and improvement has taken place almost entirely in the direction of applying in greater and greater measure scientific knowledge to methods and practices previously empirical (see **PIANOFORTE MANUFACTURE**) thus resulting in improvement in volume and richness of tone.

Summing up matters it may be said that the modern pianoforte retains six important characteristics of the clavichord, in that it has an independent sound-board (*i.e.*, the ends of the strings are not fastened to it), dampers to prevent vibration of the strings not in use, "listing" cloth to deaden the vibration from the ends of the strings beyond the bridges, groups of three strings tuned in unison and a tone production which depends upon a blow instead of a plucking (as in the spinet and harpsichord).

Five of the ideas developed in the harpsichord have also sur-

vived or have been revived from time to time, namely, the sustaining pedal, the celeste felt for soft playing, the transposing keyboard, the soft stop for practising very quietly, and the double manual (*viz.*, as recently introduced by Emanuel Moór).

As regards the sustaining pedal the importance of this cannot be over-estimated, for not only does it allow of harmonies being maintained when necessary without holding the keys down, but it also modifies the tone quality by allowing all strings to take part simultaneously by means of their resonance. Moreover the sound-board is encouraged to increase its amplitude of vibration, thus increasing the tonal volume, which in skilful hands can be made to reach a maximum intensity of over twenty times that of the most powerful harpsichord. Contrariwise, the tone can be attenuated and diminished by means of the soft pedal, which brings the hammers nearer the strings, or (as in the case of grand pianos) shifts the hammers so that they strike two instead of three strings.

The "celeste" pedal and "soft stop" devices both involve the introduction of a strip of felt between the strings and the hammers at the point of contact, thus reducing the force of the blow.

For school pianos, which are used for practising almost continuously throughout the day, the soft stop is a most useful adjunct and when properly designed need not interfere unduly with the touch of the instrument.

The transposing device, a feature of the once popular player piano, has been found both difficult to apply to the piano and to keep in perfect order owing to the necessity for shifting the keys relative to the action, a movement which upsets the delicate regulation of the repetition, and renders the device unsatisfactory.

Finally, the double keyboard, as invented by Emanuel Moór, represents a new development, possibly extending the resources of both performer and composer to some degree. Such a revolutionary departure will doubtless take time to become commercially possible, but some musical opinion is entirely in its favour. Briefly stated, the second keyboard lies just behind and above the normal standard notes, and operates those strings which are an octave higher. Consequently it is possible to play extended chords, arpeggios and double octaves with some facility. There is also an octave coupler which further increases the possibilities of the instrument from the point of view of volume. To what extent the principle will ever secure general adoption it will be rash to prophesy, but as to its ingenuity and musical value there is no room for doubt.

The principles discovered in the early actions (Erard 1821 and Robert Wornum 1826) still stand firm, and all subsequent improvements have been built thereon.

The separate parts of the modern action are produced by automatic machinery, and assembled by hand with great skill and accuracy.

The pianoforte manufacturer has long recognized the advisability of allowing this important component to be made for him

by specialists, the hammers and hammer shanks being fitted after the action has been installed.

Present-day development is largely directed towards overcoming the physical handicaps to richness and volume of tone imposed by smaller overall dimensions to fit smaller rooms. The sound-board is made as sensitive as possible, supported in a rigid frame-work which absorbs little or no energy from the board at its edges. The modern sound-board sustains a continual down-pressure from the strings of nearly half a ton, whereas the early grand pianos had scarcely a hundred-weight pressure thereon. The string tension has tripled (from 60 to 180 lb. per string in some instances) with the ability of the wire drawers to supply stronger and stronger wire, and the iron founder has had to devise castings which stand a total stress of 16 tons and upwards without occupying too much room, or covering too large a portion of the surface of the sound-board. Some early makers had the mistaken idea that an iron structure entailed the production of a "metallic" tone in the instrument; but those who adhered to the use of the wooden frame were soon left behind, mainly owing to the extreme susceptibility of the pitch of such pianos to temperature and humidity changes, which rendered the tuning very unstable.

As regards the future, experiments are now being made in the field of electrical amplification of string tone, by means of electrostatic and electro-magnetic "pick-up" devices applied to the struck strings or the structure of the piano. Amplification has so far resulted in also considerably increasing the duration of tone, causing blurred and confused results in the playing of rapid passages and staccato notes.

These effects have so far kept such new instruments acoustically outside the category of pianos due to altered tonal characteristics.

PIANOFORTE MANUFACTURE. There are eighty-eight notes in the full compass keyboard of the pianoforte, which gives a range of $7\frac{1}{2}$ octaves. The 49th tone from the bass end of the scale is called "Pitch A," and has a frequency of 440 double vibrations per second, adopted in the United States and Great Britain as the standard pitch from which all others are tuned. Since each note has to vibrate twice as fast as the note of the same name an octave below, and there are twelve semitones to the octave, it follows that the semitone ratio from note to note must be the twelfth root of 2, namely 1.05946, which is a geometrical progression giving the now generally adopted "equal temperament" tuning. Purely mathematical considerations make it essential that the string lengths should also proceed in geometrical progression, but in a slightly smaller octave ratio than 2:1. In Germany the ratio most favoured is 1.875:1, and in Great Britain 1.89:1. Both of these ratios approximately allow of half-size increases in the gauge of wire used, twice per octave, without departing far from the uniform tension initially decided upon. The English Music Wire Gauge advances one-thousandth of an inch in diameter per half size, while the New Westphalian Gauge advances 0.025 millimetre per half size, but there are irregularities in the English Gauge at various places, for reasons apparently unknown.

FIGS. 1, 2, & 3.—METHODS OF CONNECTING STRINGS TO SOUNDBOARD 1. Connecting of bass bridge to a sensitive part of the soundboard, 2. Slight dip of string after leaving bridge on its way to hitch-plate, 3. Two methods of avoiding the use of wooden-plank in extreme climates. (A) The screw pushes wrest-pin forward and holds it friction-tight, (B) the pin is held in a tapered hole by a nut

In small instruments, whether grands or uprights, it is impossible to carry theoretical string lengths throughout the piano, and compromises have to be made by shortening and thickening them in order to maintain the necessary high tension. Since short

and thick strings give a different and inferior tone quality it must not be expected that small instruments will give a pure and balanced "timbre" throughout the scale.

Cold drawn steel wire of the highest quality is specially made for the pianoforte trade, with a minimum breaking strength of 150 tons per square inch. Two types are now in favour, the polished and the plated. The latter has been successfully developed, and is especially useful for export models.

Length of Strings.—In practice the strings of the 88th note are always between 5.0 and 5.5 centimetres in length, the shorter length being used for small instruments. From this starting point the succeeding lengths are calculated mathematically until it becomes necessary to employ heavier strings weighted by means of one or two layers of copper wire closely and tightly spun upon them. In order to gain in length and to fix the bridge to a sensitive part of the sound-board, well away from its edges, about fifty of the bass strings (12 singles and 19 bichords) are planned to cross over the others, reaching to a separate and higher bridge. This method of "overstringing" is now general in all but the cheapest pianos. The lengths of the copper-covered strings are not calculated mathematically but are made so that the lowest note is as long as possible. Additional length is often secured by means of a "suspended" bridge, as shown in fig. 1, which transmits the vibrations of the bridge to a point which should be at least six inches from the edge of the sound-board.

It has been found that a tension of about 160 lb. is advisable for the uncovered strings, and the diameter of wire is calculated from the formula $\frac{\sqrt{18,600 T}}{nl}$, after which the nearest gauge to this diameter is selected, it being impracticable to manufacture a different diameter for each note. In the formula, "n" is the number of vibrations per second, "T" the tension in lb., and "l" the length of the vibrating portion of the string, in centimetres.

For the copper-covered strings some makers employ the formula $\frac{\sqrt{20,000 T}}{nl}$, which gives the all-over diameter of the required string. Others calculate the weight per centimetre instead of the diameter, using the formula $\frac{111,250 T}{n^2 l^2}$, afterwards spinning strings of the required weight, as found by experimental determinations. For bichord bass strings a considerable increase of tension is provided, varying from 10 to 15%, and for the single bass strings a further increase of 15% and upwards, according to the size of the instrument.

The Sound-board.—As the strings vibrate they transmit pressure differences to the bridge attached to the sound-board (the bridge at the other end being as rigid as possible). The large area of the sound-board is thus set in motion, and this in turn agitates the air in its immediate vicinity, the aim being to provide a sensitive and extremely elastic board, capable of reproducing the most complicated wave-forms, with as little loss of energy as possible. In addition, the board must be made of material of low density and of uniform texture.

The timber of the spruce family (*Picea excelsa*), when cut "on the quarter," answers all these requirements, the best qualities transmitting sound-waves along the grain at the rate of 16,000 feet per second and upwards. The transmission across the grain is about one-fourth of this speed, a difficulty which is surmounted by gluing bars of the same material across the back of the board at right angles to the grain. Research in the mode of vibration of the sound-board has led in the present decade to refinements in design; a new sound-board called "Diaphragmatic" is embodied in all Steinway pianos since 1937.

Most sound-boards are made with the grain running diagonally so that the long bridge runs almost parallel to the grain. The thickness is usually about $\frac{3}{8}$ " all over, some manufacturers insisting, however, that the treble end should be thicker. Sound-boards are always fitted so that they are slightly "bucked" or high in the middle, as though part of the surface of a sphere of about 60 ft. radius. This shape is secured in several ways, usually the best being to subject the board to a dry temperature of 120° F.

for some hours, and then to glue on the bars, in a slightly hollowed form.

The subsequent expansion as the board takes up its usual 10% of moisture from the air coupled with the "set" secured in the hollowed form produces the desired curvature. Since the board is always under pressure from the strings it follows that it behaves as an arch, which shape is retained through the rigidity of the rim to which it is fixed.

The "Down-bearing."—Good contact is maintained between strings and bridge by leaving the bridge a little higher than the general level of the two extremities. The resulting pressure of the strings on the sound-board is known as the "down-bearing," the regulation of which is one of the most critical processes in pianoforte manufacture. It is agreed that about one-fortieth of the tension is a suitable amount for each string to press upon the bridge. Translated into degrees this means that the bridge must stand high enough to allow the string to dip one and a half degrees after it passes over the bridge on its way to the hitch-pin on the iron frame.

Allowance has to be made for the fact that as the tension is applied the whole board is pressed down somewhat, and the amount of such sinking depends upon its dimensions, barring and support round the edge. The extra height is not measured at the bridge, but by means of a straightedge laid across where the string will pass, the amount of clearance at the hitch-pin is allowed for. (See fig. 2.) It does not matter so much what the exact pressure is, but inequalities of pressure cause very serious results, affecting those strings which lie between places of excessive pressure, and robbing them of their adequate contact with the bridge. Good contact between strings and bridge is also maintained by means of bridge-pins which lie in the line of the strings and are inserted at an angle of 70 degrees with the plane of the bridge.

By passing the string to the left of the front pin and to the right of the back pin a frictional grip is secured. This practice is almost universal, an outstanding departure being Messrs. Broadwood's method of screwing studs to the bridge and passing the strings through these. Previous efforts to provide a studded bridge have been discarded owing to the studs working loose and causing falseness of tone, but Messrs. Broadwood claim to have overcome this difficulty.

Tone and Overtones.—Pianoforte tone is compound, each note consisting of a fundamental tone and its overtones, which, sounding together, form the "harmonic series," with their vibration rates in the ratio of 1:2:3:4, etc. For instance, the tone of "middle C" has for harmonics the following notes, the frequencies of which are inserted in brackets: C (261.6), the fundamental; C (523.25), G (783.99), C (1046.5), E (1318.57), G (1567.9), B flat (1864.65), C (2093), D (2349.3) and so on. If these notes be played together as a chord it will be at once detected that the harmonics blend together pleasingly, with the exception of the seventh and ninth which are dissonant. By striking the strings at one-eighth of their length from the fixed end, it is believed that the best tone quality is produced, whether by discouraging the 7th and 9th harmonics or by encouraging the 4th is not yet scientifically proved. This strike proportion is used for all notes from the bass up to or near the 51st note, after which other considerations make it necessary to strike the string gradually nearer the end, the fraction at the extreme treble being empirically decided upon at about $\frac{1}{16}$. Since the discordant harmonics of these notes are very weak and even beyond the limits of human audition it does not matter if they are produced, the striking point being arranged to allow of a quicker recoil of the hammer from the string.

Toning the Hammers.—The process known as "toning" or "voicing" the hammers is an attempt to control the time of contact between hammer and string, a soft hammer staying long enough to damp out some of the unwanted overtones, while a hard-nosed hammer accentuates them. If a string vibrates a thousand times per second, its "periodic time" is one-thousandth of a second, and experiment proves that the best tone is emitted if the hammer is toned so that contact is maintained for about half this period.

English and German felts are used wherever the highest quality is required, their resiliency being the desirable property. Great pressure is used in modern hammer-making and the density at the treble end where the hammer dimensions are small, is more than double that of the bass hammers. The toner, by means of pricking the felt, lessens the hardness at and beneath the nose of the hammer. In this he is entirely guided by his ear, the aim being to eliminate undesirable tone components and secure an evenly graded scale, with no audible break between the treble and bass strings.

The Action.—The hammers are actuated by a system of levers known as the "action," which is now made by firms specializing in this unit alone, rather than by the piano manufacturer himself. The noses of the hammers rest at a distance of two inches from the strings, but if a note is held down after having been played, the hammer is "checked" when it has rebounded five-eighths of an inch, so that the blow can be repeated rapidly. When the key is half-way down, the felt "damper" is lifted from the strings and remains lifted until the key is released.

Pedals.—The tone is modified by means of two pedals, the left-hand pedal taking the hammers nearer to the strings and thus decreasing the force of the blow. Sometimes the whole action is shifted to the right, so that the hammer only strikes two strings instead of three. The right-hand pedal lifts all the dampers from the strings so as to sustain harmonies as long as required, and not merely for increased power. In America a central pedal is often added, called the "Sostenuto," which, instead of lifting all the dampers, affects only those which happen to be already lifted, keeping them so until the pedal is released. Thus one is able to sustain a chord, leaving the hand free for other notes.

The ideal point of contact for the dampers is at the same place as the striking point, and in grand pianos this is approximately arranged, the dampers lying along the strike line above the strings, and operated by gravity only. In upright pianos a position just under the strike line is favoured, such actions being known as "under-damper," and the pressure obtained by springs. The cheaper piano is sometimes provided with an older type wherein the damper is operated by gravity at a point just above the hammers. This is known as the "over-damper" action, and although the vibrations of the strings are of less amplitude above the hammer-line than below it, a well-made over-damper action is still in favour by certain Continental makers of repute, owing to its more effective silencing of the harmonics.

Touch.—The depth of touch for the keys has been standardized in all countries at 9 millimetres, with an additional millimetre to allow for the locking of the check and the free escapement of the "Jack" lever. The pivoting of the key has to be so placed as to give the correct amount of lift at the other end, usually about 6 millimetres, but varying a little with the different makes of action. The best "touch" is secured if the keys slope backwards a little when at rest, becoming exactly level when half depressed. At this point begins the extra load due to the lifting of the dampers, but the momentum already gained is sufficient to render it unnoticeable. A "touch weight" is used during the regulating of the action, so that when it is placed upon the end of the key, and suddenly released, the force exerted is just sufficient to make the note sound faintly. This "dead weight" of touch is not standardized, but averages 60 grammes in the bass, down to 48 grammes in the treble.

Frame.—The iron frame, which takes most of the load exerted by the pull of the 220-odd strings, is cast in one piece at the foundry, from an iron pattern which has been made 1% larger than the finished frame, in order to allow for the contraction of the casting during cooling.

Tuning Pins.—The tuning pins of mild steel, about 7 millimetres in diameter, are driven into a wrest-plank of quartered beech or maple, usually of ply construction to prevent splitting. The holes are bored slightly smaller than the pins, a ratio of 15:17 giving the correct amount of tightness. Since the plank is bolted to the iron frame and glued to the wooden back it follows that the load is shared between the frame and the back, the tendency in cheaper construction being to eliminate the wooden back alto-

gether. The wrest-plank is often covered with a web of iron into which maple plugs have been driven, the tuning pins passing through these plugs into the plank. This method has proved popular and has been adopted in many upright and grand pianos. Patent methods of securing the tuning-pins have been introduced from time to time, but the method above described would seem likely to survive all others, being efficient, inexpensive and free from complications.

For tropical climates, an all-metal wrest-plank has been designed, the wrest-pins being held "friction tight" from the back of the plank. Fig. 3 shows an Australian and a German method of providing sufficient hold for the pin, at the same time allowing it to be adjusted finely by the tuner. In order to prevent the two surfaces from rusting together, a very fine grade of graphite is used as a lubricant. The washers have a projection which fits into a slot running down the threaded portion of the pin, which ensures that they move with it during all adjustments.

FIG. 4.—STEINWAY GRAND CASE-WORK, SHOWING PARTS

Standardization.—The similarity in methods and design of the leading manufacturers in all countries is accounted for by the necessity for standardization of the keyboard, its height from the floor, the provision of room for the knees, the situation of the pedals, and the natural laws controlling the vibration of stretched strings. In the upright piano the wooden back forms a convenient base to which the ends of the case are glued, besides being the means for securing rigidity for the edges of the sound-board and a support for both iron frame and wrest-plank.

The peculiar form of the grand piano enables an immensely strong inner rim to be built up in one continuous bend, into which bracings are dove-tailed, and to which the key-bottom (supporting the key-board) is secured. This inner rim, on which the sound-board and iron frame are fastened, may be six inches deep, and from $1\frac{1}{4}$ " to $1\frac{3}{4}$ " thick. Additional rigidity is further provided by gluing this unit to an outer rim, also of ply formation, about a foot deep and from 1" to $1\frac{1}{4}$ " thick. The skeleton formation of the case-work of a large Steinway grand is shown in fig. 4, but it must be remembered that the lateral stiffness of such a structure varies inversely as the cube of its length, and therefore small grands do not need such elaborate re-inforcement, the very smallest (4 ft. 3 in. to 4 ft. 6 in. in length) often having no bracings at all. (S. A. H.; X.)

See the BIBLIOGRAPHY under PIANOFORTE; also *Grove's Dictionary of Music and Musicians*.

PIANOLA: see PLAYER-PIANO.

PIANOSA (anc. *Planasia*), an island of Italy, belonging to the province of Leghorn, and forming part of the commune of Campomare di Elba, from which it is 11 mi. S.W. Population 908. As its name indicates, it is quite flat, and the highest point is only 95 ft. above sea-level. Its area is 6 sq.mi. The discovery of numerous fossilized bones of animals show that it was still united to the mainland in the quaternary period. Traces of human habitation in the neolithic period have been found. Augustus banished to it his grandson, Agrippa Postumus, and some ruins of baths near the harbour still bear his name. It was depopulated in 1553 by the Turkish fleet, and only resettled in 1835.

PIARISTS, the popular name of a Catholic educational order, the "clerici regulares scholarum *piarum*," the Pauline Congregation of the Mother of God, founded by Joseph of Calasanza at Rome in the beginning of the 17th century. Here he organized, in 1607, a brotherhood which ultimately, in 1617, became an independent Congregation, numbering at that time fifteen priests, under Calasanza as their head. To the three usual vows they added a fourth, that of devotion to the gratuitous instruction of youth. In 1622 the Congregation received a new constitution from Gregory XV, and had all the privileges of the mendicant

orders conferred upon it. The Piarists, who are not numerous, are found chiefly in Italy, Spain, the West Indies, Germany and Austria.

PIAROAN, a linguistic substock of South American Indians belonging to the independent linguistic stock or family called Salivan.

Among the tribes belonging to the Piaroan group are the Ature (extinct), Quaquá, Macu and Piaroa proper. They are scattered along several tributaries of both sides of the middle course of the Orinoco river from the mouth of the Meta upstream to the confluence with the Ventuari river. They cultivate manioc in fields cut from the jungle and carry on hunting and fishing. Villages consist of a single circular, communal house.

By the 1950s they were reported to have mostly disappeared or to have been absorbed into other groups.

PIATRA-NEAMT, the capital of the department of Neamt, Rumania, situated on the left bank of the river Bistrita, where it cuts a way through the Carpathian foothills. Pop. (1948) 26,303.

A branch railway passes through the town, and at Bacau meets the main Czernowitz-Galatiz line. The church of St. John's (or the Prince's) monastery was founded in 1497 by Stephen the Great. There are saw mills and textile factories in Piatra, which has a considerable trade in wine and timber, and is also a popular summer resort. Neamt is one of the most densely forested regions in Moldavia.

PIATTI, CARLO ALFREDO (1822-1901), Italian violinist, was born at Bergamo, It., on Jan. 8, 1822. He was the son of a violinist, and became a pupil at the conservatorio of Milan. From 1838 onward he journeyed over Europe, playing with extraordinary success in all the important cities of the continent. He retired from public life, owing to a severe illness, in 1897.

PIAUI, a northeastern state of Brazil, bounded north and west by Maranhão, east by Ceará, Pernambuco and Bahia and south by Bahia. It has a few miles of Atlantic coast line on the north, and the Rio Parnaíba forms the boundary line with Maranhão throughout its entire length. Area, 94,819 sq.mi.; pop. (1950) 1,064,438.

Part of the state on the Atlantic coast and along the lower Parnaíba is low, swampy and malarial. South of this the country rises gradually to a high plateau with open *campos*. This plateau region is drained by numerous tributaries of the Parnaíba, chief of which are the Urussuí, the Canindé and its tributary the Piauí, the Gurgueia and its tributary the Paraim, which drains the large inland lake of Parnaguá, the Longa, and the Poti, which has its source in the state of Ceará. The Parnaíba is navigable for boats of 3 ft. draught up to Nova York, a few miles above the mouth of the Gurgueia.

The climate is hot and humid in the lowlands and along the lower Parnaíba, but in the uplands it is dry with high sun temperatures and cool nights. The principal industry is stock raising, which dates from the first settlement in 1674 by Domingos Afonso Mafrense, who established here a large number of cattle ranges. A secondary industry is the raising of goats. The agricultural products are cotton, sugar and tobacco. Much cotton is grown, and some of it manufactured. Forest products include rubber, carnaúba wax and dyewoods. The exports include hides, skins, rubber, wax, tobacco and cotton. The capital is Teresina, on the right bank of the Parnaíba, 250 mi. above Parnaíba (town), with which it is connected by a line of light-draught river boats. The town dates from 1852, is attractively situated, and is regularly laid out with broad, straight streets crossing each other at right angles. The population of the *município* in 1950 was 93,352; population of the city was 53,425. Other *municípios* with their popu-

lations in 1950 are Parnaíba (50,426); Floriano (34,677); Oeiras (45,451), founded in 1718 under the name of Moxa; Amarante (19,975); Valença (52,331); and Campo Maior (40,131). (R. D'E.; X.)

PIAVE, a river in Italy, which played an important part in the latter period of World War I on the Italian front. It rises under the Paralba pass in the Carnic Alps and flows in a south-westerly direction past Belluno as far as Feltre and then turns to the southeast, flowing into the sea at Cortellazzo to the northeast of Venice, with another, older mouth nearer to Venice. Its course is 137 mi. in length. Its depth and width vary very considerably according to the seasons of the year, a fact which had an important bearing on the operations along its banks. In its lower reaches its bed is a vast extent of gravel only filled in times of heavy rains or at the melting of the snows.

After the Austro-German break-through at Caporetto in Oct. 1917, the remains of the Italian 2nd army and all the 3rd army fell back on the Piave between Pederobba and the sea and were reconstituted behind that river. The Austrians made repeated attempts to cross the river in the November and December battles, but were eventually driven back on to the left bank. For a time some British troops held a sector of the Piave front, but they were afterward transferred to the Asiago plateau.

On June 15, 1918, the Austrians delivered a general attack along the greater part of the Italian front, known as the battle of the Piave, their object being to break through into the rich agricultural area of the Veneto. They concentrated their attacks on the sector between Falcè di Piave and Nervesa (opposite the Montello hill, rising along the right bank), and on that between the Grave di Papadopoli, a gravel-covered island in the river, and Musile. Two Austrian forces succeeded in getting across and occupied half of the Montello and some other points, but were forced by Italian counterattacks to recross the Piave, after suffering heavy losses. Later an Italian local attack resulted in the conquest of the area between the old and the new Piave near the estuary.

In Oct. 1918 an Italian offensive on a large scale was effected. The battle, which takes its name from Vittorio Veneto, east of the Piave, began on Oct. 23, but did not extend to the Piave until the 27th. On that day a small mixed Italian force crossed the river near Valdobbiadene and a part of the 10th army also crossed the Piave at the Grave di Papadopoli (this army, commanded by the earl of Cavan, comprised two British divisions). The bridges of the 8th army were swept away by the current and the regiments which had got across were isolated, and as the British forces which had crossed were not strong enough to outflank the Austrians on the dominant position of San Salvatore, Gen. Enrico Caviglia, commander of the 8th army, sent his 18th corps across on the British bridges; while that corps advanced up the river the British pushed east toward the Monticano; thus by the 29th the Austrian forces on the Piave were cut in half. On the 30th the bulk of the Italian attacking forces were across the river and the Austrians in full retreat.

PIAZZA ARMERINA, a city of Sicily, in the province of Enna, 43 mi. W. of Catania; 2,360 ft. above sea level. Pop. (1951) 26,620 (commune). It has a 16th-century cathedral, with a fine Norman campanile, and some of the houses and churches show Norman or Gothic architecture. The town was founded in the 12th century, and the inhabitants are of Lombard origin, and still speak a dialect of their own.

PIAZZI, GIUSEPPE (1746-1826), Italian astronomer, was born at Ponte, in the Valtellina, on July 16, 1746. He discovered, on Jan. 1, 1801, the first asteroid or minor planet, to which he gave the name of Ceres.

Piazzi died at Naples on July 22, 1826.

Jahrbuch*, liv, 218; *Bulletin des sciences*, vi, 339 (1826); *Edin. Journal of Science*, vi, 193 (1827); *Memoirs Roy. Astr. Soc.*, iii, 119; R. Grant, *Hist. Phys. Astronomy*, pp. 238, 510, 549.

PIBRAC, GUY DU FAUR, SEIGNEUR DE (1529-1584), French jurist and poet, was born at Toulouse. He studied law there with Jacques Cujas, and afterward at Padua. In 1548 he

was admitted to the bar at Toulouse, and rose to be *juge-mage*, an office in Languedocian cities about equal to that of *prévôt*. He was selected in 1562 as one of the three representatives of the king of France at the council of Trent. In 1565 he became general advocate to the parlement of Paris, and extended the renaissance in jurisprudence which was transforming French justice. In 1573 he was sent by Charles IX. to accompany, as chancellor, his brother Henry (afterwards Henry III.) to Poland, of which Henry had been elected king. He was employed in negotiations with the so-called *politiques*, whom he managed to keep quiet for a while. In 1578 he became the chancellor of Marguerite of France, queen of Navarre. He died in 1584.

PICA. In printing pica is a type in size smaller than "English" and bigger than "Small pica." It is also known as 12 point. The following passage is printed in pica:

Types are of various sizes, and the sizes are classified according to the dimensions of their "ems" or bodies.

"Pica" is the common standard of measurement in printing offices. The unit is a single letter of pica type called an "em."

PICARD, CHARLES ÉMILE (1856-1941), French mathematician, was born at Paris and died there. In 1878-79 he was master of conferences at the University of Paris; from 1879-81 professor at the University of Toulouse; from 1881-98 he held various positions at the University of Paris and at the École Normale Supérieure, and in 1898 became professor of higher analysis and higher algebra at the University of Paris. In 1917 he was elected permanent secretary for the mathematical sciences in the Paris Academy of Sciences.

Much of Picard's earlier work (1882-1900) centred on the theory of Fuchsian and hyperfuchsian functions, and the allied infinite discontinuous linear groups. But in 1879 he had proved the theorem known by his name, possibly of greater interest in modern analysis than his elaborate work on the various special functions fashionable in the 1880s. He proved that in the neighbourhood of an essential singularity a uniform function takes every value, with one possible exception, infinitely often. This theorem started an extensive department of analysis. He worked also in the theory of differential equations, where his most original contribution (1883, 1887) was an analogue for linear differential equations of the Galois theory of algebraic equations. Picard produced *Cours d'Analyse* which rapidly became outdated with the progress of analysis in the 20th century. (E. T. B.)

PICARD, JEAN (1620-1682), French astronomer, was born on July 21, 1620, at La Flèche, Anjou. After acting as prior of Rillé, Anjou, he went to Paris and was admitted to the Academy of Sciences as an astronomer in 1666. In 1671 he went to examine Tycho Brahe's observatory, Uranibourg, in Denmark, and returned with some of the originals of Tycho's work. Picard's measurement between Mahoisine and Amiens provided the first accurate measure of a degree of a meridian, and was used by Newton to verify his theory of gravitation. Picard founded *La Connaissance des Temps* in 1679, and edited it until his death on July 12, 1682. His works are published in the 6th and 7th vols. of the *Memoires* of the Academy of Sciences.

PICARD, LOUIS JOSEPH ERNEST (1821-1877), French politician, was born in Paris on Dec. 26, 1821, and joined the Parisian bar. In 1871 he accompanied Jules Favre to Versailles to arrange the capitulation of Paris, and in February he became minister of the interior in Thiers' cabinet. Attacked both by the Monarchist and the Republican press, he resigned in May. Later he was sent as ambassador to Brussels. On his return to Paris in 1873 he resumed his seat in the Left centre, and in 1875 became life senator. He died in Paris on May 13, 1877.

PICARDY, an old province of France, bounded on the north by Hainaut and Artois, on the east by Champagne, on the south by the Île-de-France and on the west by Normandy and the English channel. It included the whole of the basin of the Somme and part of that of the Oise. The chief towns of Picardy were Amiens, Boudgne, Abbeville, Laon, Soissons, Montreuil, Péronne, Beauvais, Montdidier, Saint Quentin and Noyon. Its bishoprics were

Amiens, Beauvais, Soissons, Noyon and Laon, and it contained the ancient abbeys of Corbie, St. Valery and St. Riquier. In 1789 Picardy was one of the provinces of the five great *fermes*. Its area now forms the *département* of the Somme and parts of the *départements* of Pas-de-Calais, Aisne and Oise.

The name of Picardy does not appear until the 13th century, and its regular organization as part of the kingdom of France dates only from the beginning of the 16th, when it was divided into northern and southern Picardy. Northern Picardy, or Picardy proper, formed one of the great military governorships of the kingdom, while southern Picardy was included in the Île-de-France.

Under the Romans, Picardy was part of Belgica Secunda; it was inhabited by the Morini, the Ambiani, the Veromandui, the Bellovacii and the Suessiones, whose names still appear in Amiens, Vermandois, Beauvais and Soissons. In the 5th century Picardy became the centre of Merovingian France: Clovis had his first capital at Soissons. Of the Carolingians, Charlemagne often resided at Noyon, and later sovereigns took refuge at Laon.

During the feudal period, Picardy was disputed among several powerful houses. The countships of Amiens and Vermandois were united to the royal domain by Philip Augustus (1191) and became the seats of two bailliages. Ponthieu (around Abbeville) became a possession of the kings of England through Edward I's marriage to its heiress. The dukes of Burgundy, after annexing the Boulonnais (1416), were anxious to possess the rest of Picardy; in 1435, by the famous treaty of Arras, the royal towns and lands in the valley of the Somme were ceded by King Charles VII to Burgundy. However, after the death of Charles the Bold in 1477 Picardy was finally united with the crown of France. The Picard towns, enriched by their export trade in corn and wood, were noted for their love of independence, which often brought them into collision with the kings of France during the 13th century. In the next century, they developed a cloth-making industry, which soon competed with that of Flanders. In the middle ages the Picards formed one of the four "nations" recognized in the organization of the University of Paris, while the Picard dialect was spoken in the whole of northern France.

PICARESQUE NOVEL, THE. This special form of the *roman d'aventures* may be defined as the prose autobiography of a real or fictitious personage who describes his experiences as a social parasite and satirizes the society which he has exploited. The picaresque, or rogue type, is represented by Encolpius, Ascylos and Giton in the *Satyricon*, which tradition ascribes to Petronius; it persists in Lucian, in the *Roman de Renart*, in the *fabliaux* and in other works popular during the middle ages. But in its final form the picaresque novel may be regarded as a Spanish invention. The word *pícaro* was first used in texts of 1541 and 1547; the etymology which derives it from *pícar* (to nibble, pick up) is unsatisfactory to philologists, although it does suggest the picaresque's chief business in life. A connection with French *picoreur* (*praedator*) is possible; and *pícaro* (a native of Picardy, with which region Spanish soldiers in the low countries had many contacts) has also been advanced, *pícaro* being the action of a *pícaro*. The earliest application of the term to a character in fiction occurs in Mateo Alemán's *Guzmán de Alfarache* (1599), a work which was long known simply as *El Pícaro*. But a genuine *novela picaresca* existed in Spain before the word *pícaro* became generally current.

Spanish Examples.—The earliest specimen of the kind is *La Vida de Lazarillo de Tormes y de sus fortunas y adversidades*, an anonymous tale in seven brief *tratados* telling of Lázaro's experiences with as many masters, alternately lay and clerical, which was long attributed, on insufficient grounds, to Diego Hurtado de Mendoza (*q.v.*). The authorship of this brilliant book and the circumstances of its first publication remain obscure; three editions appeared in 1554 and it was thrice reprinted before 1559, when it was placed on the Index for its implied attacks on the clergy. In 1555 there appeared at Antwerp *La segunda Parte de Lazarillo de Tormes*, an anonymous sequel which completely misinterpreted the irreverent wit of the original and presented the hero as a de-

vout youth transformed into a tunny. Another, more estimable, sequel, by Juan de Luna, was published at Paris in 1620. Meanwhile, many surreptitious copies of the first part were introduced into Spain; the Inquisition finally gave up the attempt to suppress it, and in 1573 an expurgated edition was authorized. Not until 1599 did a second work of the kind appear, when Mateo Alemán (*q.v.*) published the *Primera Parte de Guzmán de Alfarache*, the fictitious autobiography of the son of a ruined Genoese money-lender. The subtitle of *Atalaya de la vida humana* added to the second part explains the copious moralizings which threaten to swamp the story and contrast sharply with the laconic cynicism of *Lazarillo de Tormes*; but *Guzmán de Alfarache* is richer in invention, in variety of episode and in the presentation of character. Its extraordinary popularity tempted a Valencian lawyer named Juan José Martí to publish a *Segunda Parte* (1602) under the pseudonym of Mateo Luján de Sayavedra; in 1604 Alemán brought out the true continuation. A third part, written in Spanish by the Portuguese Felix Machado de Silva, was first printed in 1927. The *Viaje entretenido* (1603) of Agustín de Rojas, though not fiction in the accepted sense, has some claim to inclusion here. A realistic account of the writer's experiences as a strolling actor and playwright, it is, apart from its considerable literary merits, an invaluable contribution to the history of the Spanish stage as well as a graphic record of contemporary low life.

The next in chronological order of the Spanish picaresque tales is *La Pícaro Justina* (1605), the history of a woman picaroon who deceives lovers as the *pícaro* masters, which has been ascribed to Andrés Pérez, a Dominican monk; there is no good reason to suppose that the Francisco López de Ubeda on the title page is a pseudonym. The *Pícaro Justina* has wrongly acquired a reputation for indecency; its real defects are an affected diction and a want of originality. It is now read chiefly by philologists in quest of verbal eccentricities. Ginés de Pasamonte, one of the secondary figures in *Don Quixote* (1605-15), is a singularly vivid sketch of the Spanish rogue, and in the comedy *Pedro de Urdemalas* Cervantes again presents a brilliant panorama of picaresque existence. He returns to the subject in *Rinconete y Cortadillo* and in the *Coloquio de los perros*, two of the best stories in the *Novelas ejemplares* (1613), but it should be noted that the cynicism and pessimism characteristic of the kind are absent in Cervantes. In the *Viaje del mundo* (1614) the zealous missionary Pedro de Cevallos interpolates amusing tales of what befell him in the slums of Andalusia before he fled from justice to America. In *El Pasajero* (1617) Cristóbal Suárez de Figueroa fills in the sketch of the knavish innkeeper already outlined by Cervantes in *Don Quixote*. Evidence of the widely diffused taste for picaresque literature is found in *Enriquez de Castro* (1617), a story in Spanish by the Frenchman François Loubayssin de Lamarca.

The roving instinct of Vicente Martínez Espinel (*q.v.*) had led him into strange and dangerous company before and after his ordination as a priest, and his *Relaciones de la vida del escudero Marcos de Obregón* (1618) is remarkable for a baffling compound of fact with fiction written in the lucid style of which Espinel was a master; it was largely utilized by Le Sage in *Gil Blas*. Within five months of its publication at Madrid a fragmentary French version by the sieur d'Audiguier was issued at Paris, and at Paris also there appeared a Spanish picaresque story entitled *La desordenada Codicia de los bienes ajenos* (1619), by Carlos García, who reports the life story of a garrulous jailbird and appends a glossary of thieves' slang. Every kind of picaroon is portrayed with intelligent sympathy by Alonso Jerónimo de Salas Barbadillo, who is always described as a picaresque novelist; yet he so constantly neglects the recognized conventions of the Spanish school that his right to the title is disputable. Thus in *La Hija de Celestina* (1612) he abandons the autobiographical form, in *El subtil Cordobés Pedro de Urdemalas* (1620) he alternates between dialogue and verse, and in *El Necio bien afortunado* (1621) the chief character is rather a cunning dolt than a successful scoundrel. The pretense of warning newcomers against the innumerable occasions of sin in the capital is solemnly kept up by Antonio Liñán y Verdugo in his *Guía y avisos de forasteros que vienen a la corte* (1620), but in most of his tales there is more entertainment than decorum.

An unusual gravity of intention is visible in Jerónimo de Alcalá Yáñez y Ribera's *Alonso, mozo de muchos amos* (1624-26), in which the repentant *pícaro* Alonso, now a lay brother, tells the story of his past life to the superior of the monastery in which he has taken refuge.

The adventures of the ex-nun Catalina de Erauso (1592-c. 1625), who fled from her convent, dressed herself in man's clothes, went to America, enlisted in the army and was promoted lieutenant, were not published till 1829 (*Historia de la monja alférez Doña Catalina de Erauso, escrita por ella misma*) by Joaquín María de Ferrer, whose character is not a satisfactory guarantee of the work's authenticity; but its interest is unquestionable. No such suspicion attaches to the *Vida* of Alonso de Contreras, first published in 1899, in which every convention of the picaresque novel is faithfully observed, and the incidents are no doubt substantially true, though this ex-captain, like most converts, judges his own past with unnecessary harshness. This subtle form of vanity also pervades the *Comentarios del desengaño de sí mismo* of Diego Duque de Estrada, a rakish soldier and inferior dramatist whose autobiography (begun in 1614 and continued at intervals during many years) was not printed till 1860. A far higher order of talent distinguishes the *Capitulaciones de la vida de la corte y oficios entretenidos en ella*, a bitterly unsparing review of picaresque life written by the great satirist Francisco Gómez de Quevedo y Villegas (*q.v.*). These thumbnail sketches were the preparatory studies for the more elaborate *Vida del buscón Don Pablos* (1626), the cleverest and most repellent book of its class, in which, allied to profound psychological artistry, there may yet be seen a deep concern with moral values.

After *El Buscón*, whose qualities derive rather from the author than from the kind, the picaresque novel declined insensibly into the novel of adventure, with an increasing predominance of narrative over description. The *Varia Fortuna del soldado Pindaro* (1626) added nothing to the established reputation of Gonzalo de Céspedes y Meneses. Alonso de Castillo Solórzano (*q.v.*) tempted the public with three picaresque stories published in quick succession: *La Niña de los embustes*, *Teresa de Manzanares* (1634), the *Aventuras del bachiller Trapaza* (1637) and a sequel to the latter entitled *La Garduña de Sevilla* (1642). But the style was no longer welcomed with the old enthusiasm in Spain. The *Bachiller Trapaza* was destined to be continued by Mateo da Silva Cabral in Portugal and to be exploited by Le Sage, who likewise utilized in *Gil Blas* episodes taken from *El Siglo pitagórico* (1644) of Antonio Enriquez Gómez (*q.v.*). The primitive rogue returns to the scene in *La Vida y hechos de Estebanillo González* (1646). Le Sage drew upon him in the *Histoire d'Estevanillo González*.

Outside Spain.—Meanwhile, the rogue had forced his way into other European literatures. The Antwerp edition (1554) and spurious continuation (1555) of *Lazarillo de Tormes* brought the work to the notice of northern readers, and it was translated into French by Jean Saugrain in 1560 (reprinted 1561). A Dutch version was issued anonymously in 1579.

The first-known edition of David Rowland's English version is dated 1586, but as a licence to print a translation was granted on July 22, 1568-69, it is probable that a 1576 edition which appears in the Harleian catalogue really existed. Numerous reprints (1599, 1639, 1669-70, 1672, 1677) indicate that *Lazarillo de Tormes* was very popular, and that Shakespeare had read it seems to follow from *Much Ado about Nothing* (Act. II, sc. i): "Now you strike like the blind man; 'twas the boy that stole your meat, and you will beat the post." To Thomas Nash belongs the credit of writing the first picaresque novel in English, *The Unfortunate Traveller, or the Life of Jack Wilton* (1594). A reference to "Spanish pickaroos" in Thomas Middleton's *Spanish Gipsie* indicates that the picaroon type had speedily become familiar enough for London playgoers to understand the reference. Interest in picaresque literature was kept alive by James Mabbe's admirable version (1622) of *Guzmán de Alfarache*; by *The Son of the Rogue, or the Politic Thief* (1638), an anonymous translation, done through the French, of *La desordenada Codicia*; and by another anonymous translation (1657), likewise done through the French, of Quevedo's *Buscón*. One result was *The English Rogue described in the Life*

of *Meriton Latroon, a witty Extravagant* (1665), by Richard Head and Francis Kirkman.

It is not till Daniel Defoe's time that the English picaresque novel acquires any real importance. There is a female picaroon in *Moll Flanders*, and, as Defoe read Spanish, it is conceivable that she was suggested by the *Pícara Justina*; but this resemblance does not make of the book a picaresque novel. The satirical spirit which is lacking in *Moll Flanders* is, however, abundantly present in *Colonel Jacques*, which bravely aims at exhibiting "vice and all kinds of wickedness attended with misery." Henceforward the picaroon is naturalized in English literature, and is notably reincarnated in Henry Fielding's *Jonathan Wild* and in Tobias Smollett's *Ferdinand, Count Fathom*.

The Dutch translation of *Lazarillo de Tormes* (1579) did not enable the picaresque novel to strike root in Holland, yet from it is derived one of the best Dutch comedies, *De Spaensche Brabander Jerolimo* (1616) of Gerbrand Bredero. A German translation of *Guzmán de Alfarache* was published by Aegidius Albertinus in 1615; in 1627 there appeared an anonymous version of the *Pícara Justina*; and both *Lazarillo* and *Rinconete y Cortadillo* were translated by Niclas Ulenhart in 1716. The Spanish tradition was followed by Martin Frewden in a continuation (1626) of *Guzmán de Alfarache*, but the only original picaresque novel of real value in German is H. J. Grimmelhausen's *Simplicissimus*. The attempt to acclimatize the picaresque novel in Italy failed completely.

The first translation of the *Novelas ejemplares*, by Rosset and d'Audiguiet, was published at Paris in 1615; and French translations of *Guzmán de Alfarache*, of *Marcos de Obregón*, of *La desordenada Codicia*, of the *Buscón* and of the *Pícara Justina* were printed in 1600, 1618, 1621, 1633 and 1635 respectively. Paul Scarron mentions Castillo Solórzano's *Garcidía de Sevilla* in the *Roman comique* (1651), and his *Précaution inutile* and *Les Hypocrites* are convincing proofs of close study of Spanish picaresque stories: the *Précaution inutile* is taken from *Guzmán de Alfarache*, while *Les Hypocrites* is merely a translation of Salas Barbadillo's *Hija de Celestina*. The *Roman bourgeois* (1666) of Antoine Furetière is generally described as a picaresque novel, but it is concerned with the foibles of the middle class rather than with the sly devices of common vagabonds.

The Spanish picaroon lives again in *Gil Blas*, where, with a dexterity almost rarer than original genius, a master of literary manipulation fuses materials unearthed from forgotten and seemingly worthless Spanish quarries. *Gil Blas* is a creation of the gentler, sunnier French spirit; like Caron de Beaumarchais's Figaro he is a Spaniard born, reared and humanized in Paris, and these two are the only picaroons whose relative refinement has not been gained at the cost of verisimilitude. But the old original scoundrel was not yet extinct: in the interval between the appearance of the *Barbier de Séville* and the *Mariage de Figaro* Restif de la Bretonne produced a sequel (1776) to the *Buscón*—a sequel so dull as to be almost unreadable. The untamed Spanish rogue had become impossible toward the end of the 18th century; in the 19th he was deliberately rejected when Théophile Gautier wrote *Le Capitaine Fracasse*. Yet Gautier conscientiously provides a Spanish atmosphere in this, the last important book which continues the picaresque tradition. In Spanish literature elements of that tradition survived in 19th-century *costumbrismo*, and may still be met with in the novel. José María de Pereda (q.v.) in *Pedro Sánchez* (1884) touched the old theme with the accent of modernity; and the *picaro* flourished afresh in the novels of Pío Baroja (cf. *La Busca*, 1904).

In Latin-American literature the earliest novel is a genuine romance of roguery on the Spanish pattern (José Joaquín Fernández de Lizardi, *El Periquillo sarniento*, Mexico, 1816).

(J. F.-K.; W. C. AN.)

PICASSO, PABLO (1881–), the initiator of Cubism in modern painting. He was born on Oct. 23, 1881, at Malaga, Spain. His father was an artist and professor at the academy of Fine Arts at Barcelona, and under him Pablo received his first lessons in art. After many visits to Paris, he settled there in 1903. Though a Catalan by birth, he developed his art in France, where he became one of the leaders of the Post-Impressionist school.

His early work displays his gift as an illustrator of somewhat sentimental character. Like Toulouse-Lautrec he chose the subject matter of his pictures from the life of the circus and from the morbid side of life in a big city, and he rendered with feeling the strained and sad look of young soubrettes, of acrobats and harlequins. His contours were clear; his modelling in cool, greenish gray tones was almost monochrome, but assumed rose tones after 1905. He thus, from the beginning, followed a line distinct from that of Matisse and his Fauvist following, who took pleasure in colour and flat patterns, as such, and who never entirely broke with the traditions of Impressionism.

To this early period belong: "La Famille Soler" (1903), a rhythmically composed group; "l'Aveugle" (1903), archaic in the delineation of form; "La Tragédie" (1903), three gaunt, huddled figures by the illimitable sea; "La Boule" (1905), two acrobats; "La Toilette"; and a portrait of Gertrude Stein (1905–06) of the "rose period."

The Cubistic formula was evolved by Picasso and Georges Braque between 1906 and 1910, while studying the composition of still-life groups. It was Braque who first introduced into his designs bits of printed paper, delighting in the harmonious distribution of black letterpress on white paper. Picasso then added pieces of wood and other tangible objects, which led to a form of art where sculpture and painting were combined.

During Picasso's earlier Cubist period, the surfaces of his canvases were delicately toned in brown or gray by dots in pointillist fashion displaying some constructive design—mainly abstract, though here and there realistic fragments of recognizable objects were introduced. The gradations of light and dark suggested shading and space. At a later period this three-dimensional element disappeared; colour notes were introduced and the design formed a purely two-dimensional pattern.

The artist did not seek to imitate form, but to create form. As opposed to the Impressionist preoccupation with the rendering of ever-changing and superficial appearances, he wished to express the reaction of his sensibility to external objects. Carrying his convictions to the logical extreme, he discarded all resemblance to natural form, and endeavoured to create a purely abstract language of form—a visual music.

After 1918, Picasso returned mainly to traditional paths and based his pictures on natural form. His paintings became magnificently plastic and monumental. Then he changed again. Much of his work after 1925 in its fantastic and visionary character suggested sympathy with surrealism. His large mural composition entitled "Guernica" (1937) presented the tragedy of the civil war in Spain as a nightmare. Although anti-nazi, he remained in Paris during the German occupation and continued his work. After the liberation of Paris, Picasso announced that he had become a Communist. In 1949 the Paris Communist World Peace Conference adopted a dove created by Picasso as the symbol of the various Communist "peace" movements.

Picasso's inventive gift, which led him from one experiment to another, inspired many followers. Painters such as Metzinger, Gleizes, Léger, Villon, and sculptors such as Archipenko and Lipschitz, to name only a few, followed in his wake. He was one of the first to appreciate the weird expressiveness of Negro sculpture;

his style led to an appreciation of "significant form" and of constructive design in all branches of art. He became the paramount influence in modern art, besides Cézanne, who is sometimes claimed as the initiator of the Cubist movement.

Picasso's influence was also felt on the stage. He produced a series of designs for curtains, scenery and costumes for several Russian ballets. The history of his collaboration with Jean Cocteau and Erik Satie in the ballet *Parade* (1917) is told by Cocteau in *Le coq et L'Arlequin* (English trans., 1921). His work is represented in public collections in New York, Chicago, Philadelphia and in the Museum of Western Art in Moscow.

Picasso's clear, incisive outline drawings are executed with forcible directness and with rigid economy of means. He etched some plates and illustrated several books, notably André Salmon, *Le Manuscrit Trouvé dans un chapeau*; Publius Ovid, *Les Métamorphoses*; Honoré de Balzac, *Le Chef-d'œuvre inconnu*; Pepe Hillo, *Tauromaquia*. He executed portrait drawings of contemporary writers and musicians such as I. Stravinsky, J. Cocteau, M. Jacob, G. Apollinaire, A. Salmon, P. Valéry, etc. He also wrote a play, *Le Désir attrapé par la Queue* (1945; English trans., *Desire*, New York, 1948).

PICAYUNE, the name in Florida and Louisiana of the Spanish half-real = $\frac{1}{8}$ of a dollar, 6 $\frac{1}{4}$ cents, and hence used of the United States 5 cent piece; from the French *picailon*, an old copper coin of Piedmont, and possibly related to the Italian *piccolo*, little, small. In America the word is used of anything trifling or contemptible.

PICCININO, NICCOLO (1386–1444), Italian *condottiere*, born at Perugia. He served under the Visconti of Milan in campaigns against Francesco Sforza from 1425 to 1444.

PICCINNI, NICCOLA (1728–1800), Italian composer, was born at Bari, Naples, on Jan. 16, 1728. He was educated under Leo and Durante, at the Conservatorio di Sant' Onofrio in Naples. His first opera, *Le Donne dispettose*, was produced in 1755, and in 1760 he composed, at Rome, *La Cecchina, ossia la buona Figliuola*, an opera buffa which attained a European success. It was followed by many others, one of which, also an opera buffa, *Il Viaggiatori* (Naples 1774), had nearly as great a success as *La Cecchina*. In 1776 Marie Antoinette invited him to Paris. He had married in 1756 his pupil Vincenza Sibilla, a singer, whom he never allowed after her marriage to appear on the stage. All his next works were successful; but, unhappily, the directors of the Grand Opéra conceived the mad idea of deliberately opposing him, apparently against his will, to Gluck, by persuading the two composers to treat the same subject—*Iphigénie en Tauride*—simultaneously. The Parisian public now divided itself into two rival parties, which, under the names of Gluckists and Piccinnists, carried on an unworthy and disgraceful war. Gluck's *Iphigénie* was first produced on May 18, 1779. Piccinni's *Iphigénie* followed on Jan. 23, 1781, and, though performed seventeen times, was soon forgotten. Of the works of Piccinni's Paris period the best is *Didon* (1783), which kept the stage for half a century. In 1789, after the outbreak of the French Revolution, Piccinni returned to Naples, where he was at first well received by King Ferdinand IV.; but the marriage of his daughter to a French democrat brought him into irretrievable disgrace. For nine years after this he maintained a precarious existence in Venice, Naples and Rome; but he returned in 1798 to Paris, where a small place was found for him at the Conservatoire. He died at Passy, Paris, on May 7, 1800.

See P. L. Ginguené, *Notice sur la vie et les ouvrages de Niccola Piccinni* (Paris, 1801); E. Demoiresterres, *La Musique française au 18^e siècle*, Gluck et Piccinni, 1774–1800 (Paris, 1872); E. Blom, *Stepchildren of Music* (1926). For a list of his operas, which number over 80, see *Rivista musicale italiana*, viii, 75.

PICCOLO, a small flute (*q.v.*) with an extremely high range. Its highest notes reach the fourth octave above middle C and produce a shrill, penetrating sound. This quality made the B♭ piccolo, or flife (*q.v.*), popular in marching bands. Music for the piccolo is written in the same octave as that for the flute, but the sound is pitched an octave higher. The piccolo differs in construction from the flute only in the absence of low keys for C♯ and C.

PICCOLOMINI, the name of an Italian noble family, prominent in Siena (*q.v.*) from the early 13th century onward. In 1220 Engelberto d'Ugo Piccolomini received the fief of Montetari in Val d'Orcia from the emperor Frederick II as a reward for services. They obtained great wealth through trade, and established countinghouses in Genoa, Venice, Aquileia, Trieste and in France, England and Germany. Supporters of the Guelph cause in the Siennese civil broils, they were driven from the city in the time of Manfred, restored after the Angevin victories, expelled during the brief reign of Conradin and again restored with the help of Charles of Anjou. Their commercial influence passed to the Florentines. Many members of the house were distinguished ecclesiastics, generals and statesmen; two were popes, viz., Aeneas Silvius (Pius II, *q.v.*) and Francesco (Pius III, *q.v.*) Piccolomini. In 1461 Pius II's nephew Antonio Piccolomini received from Ferdinand I of Naples the duchy of Amalfi, which remained in the family till the death of Giovanni Piccolomini in 1582.

See H. M. Richter, *Die Piccolomini* (Berlin, 1874); A. Lisini and A. Liberati, *Genealogia dei Piccolomini di Siena* (Siena, 1900).

PICCOLOMINI, OCTAVIO, PRINCE (1599–1656), duke of Amalfi, Austrian general, was born on Nov. 11, 1599 in Florence, and carried a pike in the Spanish service at the age of sixteen. On the outbreak of the Thirty Years' War he served in Bohemia and Hungary, then in Spain and Italy. In 1627 he re-entered the Imperial service as colonel and captain of Wallenstein's life-guard. He was disgraced for practising extortion at Stargard in Pomerania, but his adroitness soon secured him the rank of "colonel of horse and foot." In the Mantuan War Piccolomini acted both as subtle diplomatist and as plundering soldier of fortune when Gustavus Adolphus invaded Germany.

Piccolomini was interned at Ferrara as a hostage for the ratification of a treaty, but joined in urging Wallenstein's reappointment as commander-in-chief. He was not immediately promoted on the duke's reappearance, and served under General Holk, an officer brought in from the Danish service, in the preliminary operations and in the battle of Lützen. After Lützen, the Emperor made Piccolomini a *general-feldwachtmeister*. At the same time, however, Holk was created a field marshal at Wallenstein's instance, much to his rival's chagrin. In 1633 Piccolomini commanded an important detachment posted at Königgrätz to bar the enemy's advance from Silesia into Bohemia. In May he accompanied Wallenstein on his advance into Silesia, but disapproving of the duke's policy, joined in a military conspiracy, which ended in the murder of Wallenstein (Feb. 29, 1634). Piccolomini's own part in the tragedy is commemorated in Schiller's *Wallenstein*. His material rewards for his activities in connection with the downfall of Wallenstein were his marshal's bâton, 100,000 gulden and the beautiful estate of Nachod in the Riesengebirge.

In 1638 Piccolomini was made a count of the empire, and in 1639, won a great victory over the French (relief of Thionville, July 7, 1639), was rewarded with the office of privy councillor from the emperor and with the dukedom of Amalfi from the king of Spain. But instead of being appointed, as he hoped, Gallas's successor, he was called in to act as *ad latus* to the Archduke Leopold Wilhelm, with whom he was defeated in the second battle of Breitenfeld in 1642. After this he spent some years in the Spanish service, being granted the title of grandee and the order of the Golden Fleece. Having re-entered the Imperial army, he was again disappointed of the chief command by the selection of the brave veteran Peter Melander, Count Holzapfel; but in 1648 he was at last appointed lieutenant-general of the emperor, and thus conducted as generalissimo the final campaign of the Thirty Years' War at the end of which he was made prince. He died on Aug. 11, 1656. He left no children (his only son Josef Silvio, the "Max" of Schiller's *Wallenstein*, was murdered

by the Swedes after the battle of Jankau (1645), and his titles and estates passed to his brother's son.

PICENE, $C_{22}H_{34}$, an aromatic hydrocarbon found in the products of the destructive distillation of lignite and peat tars and in the residues from the rectification of Californian petroleum. Picene crystallizes in colourless leaflets with a blue fluorescence; it melts at 364° C. and boils above 500° C. A study of its oxidation by E. Bamberger and F. D. Chattaway (1893) gave picene-quinone (an ortho-quinone) and picenic acid. The latter when distilled with lime yielded 2,2'-dinaphthyl. These facts support the above constitutional formula.

The hydrogenated picene nucleus has been shown to be present in certain natural products of the triterpenoid series. (M. S. N.)

PICENES. The Picenes do not figure at all prominently in the writings of ancient historians. They played a considerable rôle, however, in the confederacy of Italian states which challenged the hegemony of the growing Roman republic, and were punished at the end of the Social War by the complete suppression of their independence. The Picene capital was Ascoli, a little south of Ancona, on the eastern foothills of the Abruzzi.

The territory of the Picenes extended, to judge from the uniform character of the archaeological remains, all along the Adriatic coast from Rimini to the river Sangro; south of which again the Samnite mountaineers of Aufidena exhibited a civilization of identical character, though far less opulent. Inland, the Picene influence, and very probably the same population, extended as far as the midrib of the Apennines. A very ancient settlement at Terni, made long before 1000 B.C., may plausibly be attributed to them, and some writers think that they had a certain number of stations even in Latium. This would be perfectly natural if the Picenes were the principal survivors of a fairly homogeneous Neolithic population which once extended over the whole north and centre of Italy. According to this theory the Neolithic people were conquered and overwhelmed first by the invaders of the Bronze Age and then by the Villanovans (*see VILLANOVANS*). Neither of these incursions, however, penetrated further down the east coast than Rimini, at which point they were checked and diverted by the fighting forces of the Picenes.

This people retained its independence down to the third century B.C. when it finally succumbed to the Romans. It represents a phase of culture in the Early Iron Age diametrically opposed to that of the Villanovans, derived from a different source and developed under different inspiration. The first contrast between Villanovans and Picenes is in respect of their burial customs. The Villanovans cremated their dead, and the small percentage of inhumations occurring here and there within their territory may be ascribed to the survival of some few of the original Neolithic inhabitants. The Picenes on the other hand used no rite except inhumation; they buried their dead in the earth, generally in the contracted position customary among the aborigines, and cremation was entirely unknown in their part of the country.

The beginning of archaeological research in Picenum dates from the discovery by E. Brizio, in 1892, of two large and important cemeteries at Novilara, near Pesaro. Two remarkable stelae had been found in this neighbourhood 30 years earlier, with lines written in a script resembling the Etruscan in its general character, but expressing a wholly different language which is inferred to be Sabellic (*q.v.*). Several more of these stelae were found at Novilara itself, and at neighbouring places including Fano, but they still await translation. Two of them are engraved with rude but very interesting pictures of native life, representing naval battles and scenes of hunting and fighting. They are further ornamented with spiral designs, which misled earlier investigators, who saw only their superficial resemblance to sub-Mycenaean patterns. It is now established that the stelae are at any rate not older than 700 B.C.

In the Novilara cemeteries were found, besides stelae, numerous other objects and ornaments which make it possible to recon-

struct some outlines of the economic history of the Adriatic coast. About a dozen tombs at Novilara are as early as the 10th and 9th centuries B.C., while a few sporadic finds at Ancona and neighbouring points are no less ancient. From the contents of these it can be seen that the east coast of Italy was participating as early as the 10th century in the important trade in Baltic amber, which came down a main trunk route to the head of the Gulf of Venice. It can be seen also that Pesaro and Ancona were in no way dependent upon Bologna, inasmuch as many of the fibulae are of types quite unknown to the Villanovans though perfectly familiar in Greece and Sicily.

It is to commercial relations, rather than to any movement of immigration, that the composite character of Picene civilization should be attributed. In spite of the numerous details of their life which suggest analogies with the Balkans, or with Greece of the Dipylon period, there is no evidence that the population was derived, or substantially recruited, from either of these sources. The general stock of the inhabitants remained as it always had been, predominantly composed of the Mediterranean race originally derived from North Africa.

The essential characteristic of the Picenes is that they were primarily and above everything else fighting men. It has been pointed out that even before the dawn of the Iron Age they were obliged to defend their borders. They succeeded in maintaining their independence for many centuries. It is not surprising, therefore, that many tombs at Novilara contained weapons. The favourite arm was the spear, and the next in frequency was the dagger, of which there were several patterns. Swords seem to have been rather the weapons of the élite, and were extremely handsome. Helmets are fairly frequent, shields very rare, in the graves.

From graves of the 8th and 7th centuries B.C. at Novilara a complete picture may be recovered of the arms and equipment of a Picene foot soldier. His favourite sword was a broad and short weapon of iron, intended, like a sabre or a tulwar, for the heaviest cutting. Its edge was on the inside, and the hilt curved back at an angle like that of an ancient Bosnian hewing-knife. In fact there can be no doubt that swords of this kind were originally imported from the Balkans where the general type has always been well known. The curiously shaped sheath was made of wood, covered with sheets of bronze finely engraved with geometric patterns. Other swords found at Novilara are definitely Greek in origin, being of shapes familiar from the paintings on Dipylon vases. Similarly the helmets and shields are of Greek patterns, but the daggers, except when they seem to be original Italian products, follow the stock forms derived from the Hallstatt series prevalent all over Europe. The entire outfit is thus curiously hybrid in character, and quite unlike that of any other Italians. Not less characteristic than the armament of the men were the ornaments and apparel of the women. A certain number of objects were imported from the factories of Etruria or Bologna. Such are the bronze manicuring sets hung upon chateaines attached to the waist, and the bronze ear-cleaners terminating in the figure of a monkey or of Aphrodite surrounded by doves. But the narrow girdles made of chain mail in links, the huge and elaborate pendants terminating in imitation sea-shells, the handsome torques and pectorals make an ensemble quite unlike anything found among Villanovans or Etruscans.

The rich cemeteries discovered along the coast in the neighbourhood of Ancona have been little studied, and no full publication of them is yet available. All the material obtained from them may be seen in the Ancona museum, in the large buildings of a disused monastery in the city. The richest cemetery was that of Belmonte, but the collections from Cupra-marittima, Grottamare and several smaller sites are also very important. Belmonte, in particular, which dates to the 6th and 5th centuries B.C., has yielded some very fine examples of Ionic Greek work in the minor arts. There are bronze bowls decorated with figurines of cast bronze, a favourite representation being that of Herakles as the tamer of lions and horses; jugs and vessels of hammered bronze and many superb carvings in amber, of which there was a prodigal abundance at this period. At Rapagnano were found two

shield-bosses of bronze, ornamented with scenes of combat between mounted men and foot soldiers in the best Ionic style. Greek influence was entirely predominant in Picene art from the 6th century onwards, but it is important to observe that it found its way, not through Etruria, but quite directly from the Greek colonies of southern Italy. This is proved by the simultaneous presence in these tombs of the very distinctive and peculiar Apulian geometric pottery, which is unknown in Etruria.

Indeed, so far as present evidence avails, and allowing that it is dangerous to prophesy in regard to a region only partially explored, Etruscan influence on the Adriatic coast was very slight and unimportant. A tumulus of the 7th century found at Fabriano is almost entirely Etruscan in its contents, but as yet this is an isolated example. A certain amount of trade was undoubtedly carried on across the Apennines, but there is little in the general complex of Picene life which suggests a strong Etruscan impress. On the contrary, it remains a curiously individual and virile civilization, in spite of its many borrowings. The backbone of Picene commerce was constituted by a lively trade with Istria, which may be clearly traced by means of a comparative study of the objects found in the graves. Nothing, except the existence of a trade-system which centred at the head of the Gulf of Venice, could explain the remarkable circumstance that, in places as far apart as the Italian lakes, Istria, Picenum and Bosnia, there have been found torques, pendants and amulets so precisely similar that they must have been distributed by the same firm of agents.

See E. Brizio in *Monumenti Antichi*, vol. v.; D. Randall-MacIver, *The Iron Age in Italy* (1927); and for a literary treatment from other points of view, F. von Duhn, *Italische Gräberkunde*, vol. i. (1924). (D. R.-M.)

PICENUM, a district of ancient Italy, situated between the Apennines and the Adriatic, bounded north by the Senones and south by the Vestini. The whole territory was divided up among Latin-speaking settlers by the Lex Flaminia in 232 B.C.

It was in Picenum (at Asculum) that the Social War broke out in 90 B.C. Under Augustus it formed the fifth region of Italy, and included twenty-three independent communities. It was reached from Rome by the Via Salaria and the Via Caecilia.

At the end of the 2nd century A.D. the north-eastern portion of Umbria acquired the name Flaminia, from the high road. For the time it remained united with Umbria for administrative purposes, but finally passed to Picenum in the time of Constantine, and acquired the name of *Flaminia et Picenum Annonarium*, the main portion of Picenum being distinguished as *Suburbicarium*. When the exarchate of Ravenna was founded the part of Picenum Annonarium near the sea became the Pentapolis Maritima, which included the five cities of Ariminum, Pisaurum, Fanum Fortunae, Sena Gallica and Ancona. The exarchate was seized by Luitprand in 727, and Ravenna itself was taken by Aistulf in 752. In 753, however, the Emperor Pepin handed it over to the pope, a grant confirmed by Charlemagne.

PICHEGRU, CHARLES (1761-1804), French general, was born at Arbois, or at Les Planches, near Lons-le-Saulnier, on Feb. 16, 1761. His father was a labourer, but the friars of Arbois gave the boy a good education, and the Père Partault took him to the military school of Brienne. In 1783 he entered the first regiment of artillery, where he rapidly rose to the rank of adjutant-sub-lieutenant. At the Revolution he became leader of the Jacobin party in Besançon, and when a regiment of volunteers of the department of the Gard marched through the city he was elected lieutenant-colonel. Quickly promoted to the command of the army of the Rhine, in co-operation with Hoche and the army of the Moselle, Pichegru reconquered Alsace and forced the lines of Haguenau and relieved Landau. In Dec. 1793 Hoche was arrested and Pichegru became commander-in-chief of the army of the Rhine-and-Moselle, succeeding Jourdan in the army of the North in Feb. 1794.

It was now that he fought his three great campaigns of one year. The English and Austrians held a strong position along the Sambre to the sea. After vainly attempting to break the Austrian centre, Pichegru suddenly turned their left, and defeated

Clerfayt at Cassel, Menin and Courtrai, while Moreau, his second in command, defeated Coburg at Tourcoing in May 1794; then after a pause, during which Pichegru feigned to besiege Ypres, he again dashed at Clerfayt and defeated him at Rousselaer and Hooglede, while Jourdan came up with the new army of the Sambre-and-Meuse, and utterly routed the Austrians at Fleurus on June 27, 1794. Pichegru began his second campaign by crossing the Meuse on Oct. 18, and after taking Nijmegen drove the Austrians beyond the Rhine. Then, instead of going into winter-quarters, he prepared his army for a winter campaign. On Dec. 28 he crossed the Meuse on the ice, and stormed the island of Bommel, then crossed the Waal in the same manner, and, driving the English before him, entered Utrecht on Jan. 19 and Amsterdam on Jan. 20, and soon occupied the whole of Holland. The former friend of Saint Just now offered his services to the Thermidorians, and after receiving from the Convention the title of "Sauveur de la Patrie," subdued the *sans-culottes* of Paris, when they rose in insurrection against the Convention on 12 Germinal (April 1). Pichegru then took command of the armies of the North, the Sambre-and-Meuse and the Rhine, and crossing the Rhine in force took Mannheim in May 1795.

When his fame was at its height he allowed his colleague Jourdan to be beaten, betrayed all his plans to the enemy, and took part in organizing a conspiracy for the return of Louis XVIII. His intrigues were suspected, and when he offered his resignation to the Directory in Oct. 1795, it was promptly accepted. He retired in disgrace. In the Council of Five Hundred (May 1797) he was the royalist leader, and planned a *coup d'état*, but on the 18th Fructidor he was arrested, and deported to Cayenne in 1797. Escaping, he reached London in 1798, and served on General Korsakov's staff in the campaign of 1799. He went to Paris in Aug. 1803 with Georges Cadoudal to head a royalist rising against Napoleon; but was arrested on Feb. 28, 1804, and on April 15, was found strangled in prison. He was a man of enormous strength and great personality.

There is no really good life of Pichegru; perhaps the best is J. M. Gassier's *Vie du général Pichegru* (1815). For his treason, trial and death, consult Montgaillard's *Mémoires concernant la trahison de Pichegru* (1804); Fauche-Borel's *Mémoires; Savary, Mémoires sur la mort de Pichegru* (1825); and G. Pierret, *Pichegru, son procès et sa mort* (1826); and Sir J. R. Hall, *General Pichegru's Treason* (1915).

PICHER, a city of Ottawa county, Oklahoma, U.S.A., in the northeastern corner of the state, near the Kansas boundary; on federal highway 69 and served by the Northeast Oklahoma (electric) and Frisco railways. The population was 3,951 in 1950 and 5,858 in 1940 by the federal census. It is one of the principal mining centres in a tristate region which produces much of the zinc and lead mined in the United States.

Picher was built entirely on leased land, owned by the Quapaw Indians. The first mine was opened in 1915. The city was incorporated in 1920.

PICKENS, ANDREW (1739-1817), American soldier in the Revolutionary War, was born in Paxton, Pa., on Sept. 19, 1739. His family settled at the Waxhaws (in what is now Lancaster county), S.C., in 1752. He fought against the Cherokees in 1761 as a lieutenant. In the Revolutionary War he rose to brigadier-general (after Cowpens) in the South Carolina militia. On Feb. 14, 1779, with 300-400 men, he surprised and defeated about 700 Loyalists on Kettle Creek, Wilkes county, Ga.; and later in the same year at Tomassee defeated the Cherokees, who were allied with the British. Upon the surrender of Charleston (May 1780) he became a prisoner on parole, which he observed rigidly until, contrary to the promises made to him, Maj. James Dunlap plundered his plantation; he then returned to active service. His command (about 150 men) joined Gen. Daniel Morgan immediately before the battle of Cowpens, in which Pickens commanded an advance guard (270-350 men from Georgia and North Carolina) and twice rallied the broken American militia; for his services Congress gave him a sword. With Col. Henry Lee he harassed Lieut.-col. Banastre Tarleton, who was attempting to gather a Loyalist force just before the battle of Guilford court house; and with Lee and others, he captured Augusta (June 5, 1781) after a siege. At Eutaw Springs (Sept. 8, 1781) he commanded the left wing and was

wounded. In 1782 he defeated the Cherokees again. After the war he was active for several years in state politics, and in 1793-95 was a representative in congress. He died in Pendleton district, S.C., Aug. 17, 1817.

PICKENS, FRANCIS WILKINSON (1805-1869), U.S. politician, was born in Togadoo, St. Paul's parish, S.C., April 7, 1805, grandson of Gen. Andrew Pickens (*q.v.*). He was educated at Franklin college, Athens, Ga., and at South Carolina college, Columbia, and was admitted to the bar in 1829. In 1832 he was elected to the state house of representatives, where he submitted a report denying the right of congress to exercise any control over the states. He was a Democratic member of the national house of representatives in 1834-43, served in the South Carolina senate in 1844-45, was U.S. minister to Russia in 1858-60, and in 1860-62 was governor of South Carolina. He strongly advocated the secession of the Southern states and signed the South Carolina ordinance of secession; he sanctioned firing upon the "Star of the West" (Jan. 9, 1861), which was bringing supplies to Anderson, and the bombardment of Ft. Sumter. He died at Edgefield, S.C., Jan. 25, 1869.

PICKEREL, the name used, especially in the United States, where there are several species which never reach a large size, for certain small pike (*q.v.*). In England small specimens of *Esoc lucius*, the only species represented, are usually termed jacks.

PICKERING, EDWARD CHARLES (1846-1919), U.S. physicist and astronomer, was born in Boston, Mass., July 19, 1846. He was graduated in 1865 in the Lawrence Scientific school of Harvard, where for the next two years he was a teacher of mathematics. Subsequently he became professor of physics at the Massachusetts Institute of Technology, where he established the first U.S. laboratory in which students were instructed by actual contact with physical instruments and measurements. In 1876 he was appointed professor of astronomy and director at the Harvard college observatory. In 1877, when most observatories were devoting themselves to the old "astronomy of position," Pickering, who was a physicist rather than an old school astronomer, chose as his particular field of labour the photometry of the stars, thus pre-empting the trend of the new astronomy along lines of physics. He invented the meridian photometers (*see* PHOTOMETRY, CELESTIAL), with which the brightness of more than 45,000 stars was measured at Cambridge and Arequipa (Peru) observatories, and the resulting system was generally adopted as an international standard. Pickering himself made more than 1,500,000 photometric settings.

Through the establishment of an observatory at Arequipa (1891), after two years of study it became possible to include measurements made on the stars throughout the southern heavens within the scope of the Harvard college observatory's work.

The work of the observatory under Pickering may be summarized as including photometry; a scale of photographic magnitude; a system of classification of variable stars; and a system of stellar spectroscopy which was universally adopted. He died at Cambridge, Mass., Feb. 3, 1919.

PICKERING, TIMOTHY (1745-1829), U.S. politician, was born at Salem, Mass., on July 17, 1745. He graduated from Harvard college in 1763 and was admitted to the bar in 1768. In the pre-Revolutionary controversies he identified himself with the American Whigs; and in 1776 he was a representative from Salem in the general court of Massachusetts. Early in 1775 he published *An Easy Plan of Discipline for a Militia*. In the same year he became judge of the court of common pleas for Essex county, and in the winter of 1776-77 he led an Essex regiment of volunteers to New York. He subsequently served as adjutant general, later as quartermaster general and was also a member of the board of war. In April 1783 he drew up a plan for the settlement of the Northwest territory, which provided for the exclusion of slavery. In 1785 he became a commission merchant in Philadelphia; but in Oct. 1786, soon after the legislature of Pennsylvania had passed a bill for erecting Wyoming district into the county of Luzerne, he was commissioned to organize the county. He offered to purchase for himself the Connecticut title to a farm, and in 1787 he was appointed a member of a commission to settle claims according to the terms of an act, of which he was the author, confirming the Connecticut titles (*see* WYOMING VALLEY, WILKES-BARRE). In 1790 he negotiated a peace with the Seneca

Indians; he concluded treaties with the Six Nations in 1791-94. Under Washington he was postmaster general (1791-1795), secretary of war (1795), and after Dec. 1795, secretary of state, to which position he was reappointed (1797) by Adams.

In 1783, while he was quartermaster general, he had presented a plan for a military academy at West Point, and, as secretary of war, he supervised the West Point military post with a view to its conversion into a military academy. As head of the state department he soon came into conflict with Adams, and opposed the president's efforts to settle peaceably the differences with France. He was dismissed, after refusing to resign, in 1800. Returning to Massachusetts, he was elected a United States senator, 1803-11, and a member of the house of representatives, 1813-17. As an ultra Federalist—he was a prominent member of the group known as the Essex Junto—he strongly opposed the purchase of Louisiana and opposed the War of 1812. He died at Salem, Mass., on Jan. 29, 1829.

See his biography by his son, Octavius Pickering (1791-1868); C. W. Upham, *The Life of Timothy Pickering* (Boston, 1867-1873).

PICKERING, WILLIAM HENRY (1858-1938), U.S. astronomer, was born in Boston, Mass., on Feb. 15, 1858, and in 1879 graduated at the Massachusetts Institute of Technology. He served there as an assistant and instructor in physics from 1880 to 1887, and then became an assistant in astronomy at the Harvard college observatory. In 1889 he was made assistant professor of astronomy. He led expeditions for observing total solar eclipses to Colorado, 1878; Grenada, West Indies, 1886; California, 1889; Chile, 1893; and Georgia, 1900. While in southern California in 1889 he selected the Mt. Wilson site and established a temporary observatory there. In 1891 he established the Arequipa station of the Harvard observatory in Peru. He also established a meteorological station at an altitude of 16,650 ft. upon Mt. Chachani, and accomplished the ascent of El Misti, 19,167 ft. He surveyed and determined the altitude of many other Peruvian mountains and returned to the United States by way of the Straits of Magellan in 1893. In 1894 he erected the observatory and telescope for Dr. Percival Lowell (*q.v.*) at Flagstaff, Ariz., and in 1900 erected a station for the Harvard observatory at Mandeville, Jamaica, in the West Indies. In 1899 he discovered Phoebe, ninth satellite of Saturn, and explained its contrary revolution. In 1904 he again went to California to make observations of the moon, in 1905 to Hawaii, and in 1907 to the Azores to compare their crater formations with those in the moon. His work in planetary photography and photometry was especially notable. Pickering died in Jamaica, Jan. 21, 1938.

PICKERING, an urban district in the North Riding of Yorkshire, Eng., 26 mi. north-northeast of York by road. Pop. (1951) 4,336. Area 24.4 sq.mi. The town, lying on the southern edge of the Yorkshire moors at the entrance to one of the riverways into the Vale of Pickering, is a tourist centre for the moors. It is also the centre of an agricultural, horticultural and pastoral area, with a broad belt of arable land in the vale, given to cereal and fodder crops; and a moorland grazing area to the north. Agricultural implements are made and limestone and freestone are quarried in the vicinity. A castle existed at Pickering before the Conquest; the present ruin is partly Norman but mainly 14th century work. It was the prison of Richard II before his confinement at Pontefract. During the civil wars it was held by the royalists and suffered greatly in siege.

PICKETING: *see* STRIKES AND LOCKOUTS; TRADE (LABOUR) UNIONS.

PICKETT, GEORGE EDWARD (1825-1875), U.S. and Confederate army officer, whose division made the famous charge at the battle of Gettysburg, was born at Richmond, Va., Jan. 25, 1825. Upon graduation from West Point in 1846 he was assigned to the 8th United States infantry; he served with distinguished valour in all the battles of Gen. Winfield Scott in Mexico, including the siege of Vera Cruz and the storming of Chapultepec, where, it is said, he was first to scale the parapets and unfurl the U.S. flag over the castle. After peace was restored, Pickett was transferred to Washington territory where he played an important role in the north-west boundary controversy. In 1859 he was ordered to occupy San Juan Island, where he prevented the landing of a superior force of British troops. On the outbreak of the Civil War he resigned his command (June 1861) and offered his services to the Confederacy. He was commissioned captain and after a short time was made a colonel. In Feb. 1862 he was appointed a brigadier general and assigned to the command of a

Virginia brigade of infantry. During that year he rendered able service in the battles of Williamsburg, Seven Pines, Gaines Mill and Fredericksburg. While leading his men at Gaines Mill he was severely wounded, but upon returning to his command in September he was made a major general. At Gettysburg his division was held in reserve until July 3, when it led the attack on Cemetery hill. The charge of Pickett's men is one of the most famous episodes of military history. More than three-quarters of the division, 3,393 officers and men out of 4,500, were left on the field. He subsequently commanded the Confederate forces in North Carolina but after the failure to take New Bern, he turned north to defend Petersburg. His troops participated in the assault on Gen. Ulysses Grant's line at Cold Harbor and in the closing campaign of 1865 at Dinwiddie court house and Five Forks. After the Civil War he went to Richmond and later to Norfolk where he was engaged in the insurance business. He died in Norfolk, Va., July 30, 1875.

See La Salle Corbell Pickett, *Pickett and his Men* (rev. ed., 1913).

PICKFORD, MARY (1892—) (stage name of Gladys Smith), U.S. motion-picture actress noted for her roles as an ingénue, was popularly known as "America's sweetheart." Born at Toronto, Ont., April 8, 1892, she made her first stage appearance at the age of five; at eight she went on tour. She went to New York under the auspices of David Belasco, creating the part of Betty Warren in *The Warrens of Virginia*. Her first motion-picture work, as an extra, was undertaken with David W. Griffith; but she returned to Belasco, taking the part of Juliet in *A Good Little Devil* at the Republic theatre in New York. In 1913 she returned to the screen with Famous Players company, rising to first rank. In 1916 the Mary Pickford Film corporation was organized. In 1918 she became an independent producer and in 1919 was prime mover in forming the United Artists corporation. She married Douglas Fairbanks in 1920, was divorced in 1935, and married Charles Rogers in 1937.

PICKLEWEED: see IODINE-BUSH.

PICKLING is a general term meaning to preserve in salt, acid, sugar, or any combination of the three. The word appears to be an adaption of the Dutch *Pekel*, "brine, pickle" (cf. Ger. *Pökel*). The term is applied to the preservation of wood by treating it with Dovicides, creosote, or copper or zinc sulphate or similar solutions. Certain kinds of steel are pickled in sulphuric acid; the term may also refer to processes in metal casting and leather manufacturing.

The greatest use of pickling is in the food industry where it is one of the four (canning, freezing and dehydrating are the others) most commonly used methods of preserving food. In the preparation and preservation of fish, meat, especially pork, and meat products such as bologna, wieners, sausages, etc., a brine made of salt (sodium chloride), sodium nitrite and sodium nitrate is widely used. Eggs are sometimes pickled in limewater (calcium hydroxide) or in water glass (sodium silicate).

Fruits, nuts and vegetables are pickled in a variety of ways. Crab-apples, peaches, pears and watermelon rind are pickled in a solution of vinegar, spices and sugar. Unripe walnut meats are pickled in salt, sugar and acid. Onions, cauliflower and mango peppers are pickled in strong (20–24%) salt without fermentation. Other vegetables, such as cabbage (2% salt), green tomatoes and certain kinds of peppers (e.g., banana, finger and tomato peppers [5–10% salt]), undergo a lactic fermentation and are preserved by a combination of acid and salt.

Cucumber pickles are by far the most popular kind of pickles in the United States. Two varieties of cucumbers are used: the white spine, which has a thick, smooth, dark green skin and is the produce variety used for slicing; and the smaller black spine, which has a thin, warty, light green skin and is grown especially for pickling. All types of fresh cucumber pickles are made by placing fresh, washed cucumbers (whole or sliced) in glass jars, adding salt, acetic acid, sugar, turmeric, alum and spices, and then pasteurizing; other processes are used for salt stock and for fermented cucumber pickles.

(F. W. FN.)

PICO, an island in the Atlantic ocean, belongs to Portugal, and forms part of the Azores archipelago. Pop. (1950) 22,557; area 167 sq.mi. Pico rises to the height of 7,713 ft. The soil is

of volcanic origin. The island was formerly famous for its Fayal wine (Fayal is, however, an adjacent island), but in 1852 the vines were destroyed by disease. Similar destruction affected the fruit trees (orange) and a period of emigration followed. The distress was alleviated by the planting of fig trees and the cultivation of apricots. The chief town is Lagens do Pico.

PICO DELLA MIRANDOLA, GIOVANNI, COUNT (1463–1494), Italian philosopher and scholar, was next in importance to Marsilio Ficino (q.v.) as an exponent of Renaissance Platonism and is still admired as a representative of Renaissance learning. He was born on Feb. 24, 1463, the youngest son of Giovanni Francesco Pico, prince of Mirandola, a small territory not far from Ferrara. Pico, who was a precocious child, received a thorough humanistic education at home and subsequently studied canon law at Bologna and Aristotelian philosophy at Padua. He also visited Florence and Paris and learned Hebrew, Aramaic and Arabic. Introduced by his Hebrew teachers to the Jewish Kabbalah, Pico was the first Christian scholar who tried to use Kabbalistic doctrine in support of Christian theology. In 1486 he proposed to defend in a public disputation in Rome 900 theses drawn from diverse Greek, Arabic, Hebrew and Latin thinkers, and composed for that occasion his famous *Oration* on the dignity of man; but 13 of the theses were declared heretical by a papal commission, and the disputation was prohibited by Pope Innocent VIII. Pico tried to defend the theses in an *Apologia* and fled to France. On the request of Lorenzo de' Medici, he was allowed to settle in Florence where he was connected with the famous Platonic Academy. There he spent the rest of his life except for short trips to Ferrara. He was absolved from the suspicion of heresy by Pope Alexander VI in 1493.

Pico published an exposition of Genesis under the title *Heptaplus* (Florence, n.d.); worked on a harmony of Plato and Aristotle, of which the completed treatise *De Ente et Uno* was part; and began a treatise against the enemies of the church, which included his famous and influential work against the astrologers. Toward the end of his life, he came under the influence of Girolamo Savonarola. He died in Florence on Nov. 17, 1494. Although his early death prevented Pico from working out his philosophy, his writings contain significant and influential ideas. He found elements of truth in all the different schools and thinkers known to him and defended the merits of the mediaeval scholastic philosophers against Ermolao Barbaro (q.v.). In exalting the dignity of man, he denied that man occupies any fixed place in the universal hierarchy, but asserted that he determines his place and nature through his own free choice. His critique of astrology was based on religious rather than on scientific considerations and failed to gain general acceptance at the time, but it contained a good deal of weighty detail and influenced Johann Kepler in the 17th century.

BIBLIOGRAPHY.—The first great collection of Pico's writings was the *Commentationes Joannis Pici Mirandolae*, ed. with a biography by his nephew Giovanni Francesco Pico, 2 parts (Bologna, 1495–96); of the modern edition by E. Garin, 3 vol. have appeared (Florence, 1942–52). Some of the letters and the biography were translated by Thomas More (1510?). See further E. Garin, *Giovanni Pico della Mirandola* (Florence, 1937); E. Anagnine, *G. Pico della Mirandola* (Bari, 1937); P. Kibre, *The Library of Pico della Mirandola* (New York, 1936); A. Dulles, *Principes Concordiae* (Cambridge, Mass., 1941); J. Blau, *The Christian Interpretation of the Cabala in the Renaissance* (New York, 1944). (P. O. K.)

PICRIC ACID or LYDDITE, is a yellow crystalline solid melting at 122.5° C.; it owes its name to the intensely bitter and persistent taste of its yellow aqueous solution. As experiments regarding the use of picric acid as a high explosive were once conducted at the town of Lydd (Sussex), the name Lyddite became attached to the acid. The term mellinite is employed in France and Germany, and shinosite indicates the Japanese variety of this explosive. As its graphic formula (inset) indicates, it is a benzenoid derivative with three hydrogen atoms of the benzene nucleus replaced by nitro (NO₂) groups, and one replaced by a hydroxyl (OH) group, whence its name and formula 2:4:6 trinitrophenol HO.C₆H₂(NO₂)₃. It is a typical example of a nitro compound of the aromatic series, and was formerly employed as an acid dyestuff giving yellow shades on wool or silk. Although acting as a poison when administered in quantities exceeding a few milligrams, its saturated aqueous solution may safely be applied to burns and scalds with the object of subduing the pain, which

it effects by paralysing the sensory nerve endings.

The ordinary method of manufacturing picric acid is to dissolve phenol in strong sulphuric acid thus making a phenolsulphonic acid, $C_6H_5OH + H_2SO_4 = HO.C_6H_4.SO_3H$, which on treatment with a moderate excess of nitric acid regenerates sulphuric acid, and at the proper temperature gives finally trinitrophenol. This separates as an oily liquid which becomes solid on cooling. It is washed with cold water to remove excess of acids and then dissolved in hot water, from which it crystallizes in yellow scales, plates or needles, depending on the concentration of solution. The picrates of ammonia and of the alkali metals sodium and potassium are most soluble, whereas the lead salt and a few others are sparingly soluble in water. Certain organic bases, such as acridine, give more insoluble salts than metals. When heated above its melting point picric acid puffs or burns with a smoky flash: a small amount may sublime as a yellow powder. This burning does not appear to be dangerous when only small quantities are dealt with unless the external heating be rapid and extensive, so that the whole bulk under experiment is heated up; in that case the simple burning passes over into a kind of detonating decomposition. The metallic salts of picric acid are most liable to this violent form of explosion, in fact it is almost the only form of explosion they exhibit either on heating or under percussion. The picrates of lead, bismuth and other heavy metals are extremely sensitive to friction or percussion as well as heating, especially when dry. The pure acid itself is not dangerously sensitive to percussion, although a powerful and quick glancing blow will often induce decomposition. The explosion of a very small amount of a picrate—as the lead or potassium salt—in contact with the acid, especially if the latter be in a compact state, generally induces a complete detonation. At one time picric acid was much in favour either as an ingredient of an explosive mixture with some special objective use or alone. Among the mixed explosives containing picric acid may be mentioned Brugères powder, a mixture of 54 parts of ammonium picrate and 45 of potassium nitrate; Designolles' powder, potassium picrate, potassium nitrate and charcoal; and emmensite, of similar composition, suggested by Stephen H. Emmens of the United States. Many others were designed for blasting or similar purposes. (W. R. Ho.)

PICRITE, in petrology, an intrusive igneous rock of ultrabasic composition somewhat similar to peridotite (*q.v.*). The name, given by Gustav Tschermak von Seysenegg in 1866, is derived from *πικρός*, "bitter," because of the high percentage of magnesia (bitter earth) these rocks contain. The picrites are dark, heavy rocks largely composed of olivine and augite, with a small but variable amount of plagioclase feldspar. Hornblende and biotite may also be present. The picrites usually occur in sills or sheets, and seldom in large plutonic masses (unlike peridotites). Varieties of picrite include augite, enstatite and hornblende picrite.

The minerals of picrites are very frequently decomposed. Serpentine partially or wholly replaces olivine, while hornblende (pilitite), talc and chlorite appear as secondary products after the same mineral. Augite passes into hornblende or chlorite, and the essential feldspar is often represented by epidote, prehnite and white mica. In some picrites, as in the peridotites, a lustre mottling is given by the poikilitic inclusion of olivine grains in large crystals of augite or hornblende. In the porphyritic varieties a residual brown glass may be present. Such rocks are known as picrite-porphyrates.

Many picrites clearly possess alkaline affinities. Thus the augite picrites of the Midland valley of Scotland and of the type locality in Moravia contain interstitial analcime and are closely related to the teschenites with which they are associated. Other picrites are more clearly calc-alkaline, being associated with diorites or dolerites. The hornblende picrites of Caernarvonshire, Anglesey and other places belong here. In the Devonian rocks of the Fichtelgebirge and Nassau picrites accompany dolerites and proterobasals, as they do also in Cornwall and Devon.

The term picrite-basalt is reserved for feldspar-poor basalts rich in olivine. (C. E. T.)

PICROTOXIN, a neutral principle occurring in *Cocculus*

indicus, the berry of *Anamirta cocculus*, indigenous to Malabar and the East Indies. The berries are also known as fishberries because of their use by the natives for poisoning fish. Because of their bitter and intoxicating properties, they have been added to beer and used externally as an antiparasitic, but their extreme toxic properties make these uses dangerous. Picrotoxin is an equimolecular compound of picrotin and picrotoxinin, the latter representing the active part. Its effects are somewhat similar to those of strychnine, except that the action of strychnine is predominantly on the spinal cord while that of picrotoxin is on the cortex and medulla. In small doses it stimulates and in larger doses depresses the central nervous system, so that the sequence of events in picrotoxin poisoning are convulsions, confusion and unconsciousness. The only justifiable use for picrotoxin is as an antidote in poisoning by central nervous system depressants, especially the barbiturates, in which case its stimulating action on the respiratory system acts as an effective physiological antagonist. Conversely, in picrotoxin poisoning, barbiturates, chloral hydrate or chloroform are indicated.

PICTISH. The language of the ancient Picts is of uncertain origin and of doubtful affinity. "The Picts have left us a number of inscriptions in the Ogham character. No attempt to interpret these inscriptions as any form of Celtic has produced anything but bosh! Whatever may have been the Pictish language, these inscriptions assure us that it was certainly not Celtic." (R. A. S. Macalister in *Antiquity*, ii, 7, p. 373, 1928.) Examination of the symbols found upon monumental stones in Pictland suggests analogies with certain elements in Bronze Age sculpturings—a highly probable affinity if the Picts were the survivors of Bronze Age aborigines, influenced by La Tène culture.

The term *Pict* itself may be connected with the Latin *Pictones* and *Pictari* of Gaul. In Irish they are known as *Cruithne*, in Welsh as *Prydyn*, which (*cf.* Prydein, or British) significantly resembles the earliest Greek name for the British Isle, *Pretannic Islands*. From the matrilineal succession of their chiefs (the records being doubtful) it has been inferred that their social structure differed from that of other Gaelic speaking peoples. Pictish extended to the north of Ireland, and was finally ousted by the Goidelic speech of the Scots, which was derived from Ireland.

See T. R. Holmes, *Caesar's Invasion of Britain* (1907).

PICTOGRAPHY. In the history of writing a very large number of conventional marks are demonstrably reductions from still older forms, which have often developed out of pictographs. Pictography has left its traces in all parts of the world, but was most widely developed in the New World as a system lasting down to modern times.

Very simple pictures are drawn upon birch bark, indicating by their order the subjects in a series of song-chants with sufficient precision to enable the singer to recall the theme of each in his recitation. An account can be kept of sales or purchases by representing in perpendicular strokes the number of items, and adding at the end of each series a picture of the animal or object to which the particular series refers. Thus three strokes followed by the picture of a deer indicate that the hunter has brought three deer for sale. A conventional symbol (a circle with a line across it) is used to indicate a dollar, a cross represents ten cents, and an upright stroke one cent, so that the price can be quite clearly set forth. This practice is followed in many other parts of the world. In clay tablets discovered by Sir Arthur Evans at Knossos, in Crete, a somewhat similar method of enumeration is followed; while at Athens conventional symbols were used to distinguish drachmae and obols upon the revenue records.

In comparatively recent times the Dakota Indians invented a chronological table, or winter count, wherein each year is recorded by a picture of some important event which befell during that year. In these pictures a considerable amount of symbolism was necessary. A black upright stroke indicates that a Dakota Indian was killed, a rough outline of the head and body spotted with blotches indicates that in the year thus indicated the tribe suffered from smallpox. Sometimes, in referring to persons, the symbol is of the nature of a rebus. Thus, Red Jacket, an Indian chief, was killed in the winter of 1807-8; this fact is recorded by a red coat

with two arrows piercing it and blood dripping. There is, however, nothing of the nature of a play upon words intended. Here the Mexicans proceeded a stage further, as in the often quoted case of the name of Itz-coatl, literally knife-snake, which is ordinarily represented by a reptile (*coatl*) with a number of knives (*itz*) projecting from its back. It is, however, also found divided into three words, itz-co-atl—knife-pot-water—and represented by a different picture accordingly. The Mexicans, moreover, to indicate that the picture was a proper name, drew the upper part of the human figure below the symbol, and joined them by a line, a practice adopted also among their northern neighbours when, as in names like Little-Ring, the representation would hardly be sufficiently definite. Simple abstract notions could also be expressed in this picture-writing. Starvation or famine was graphically represented by a human figure, with the ribs showing prominently. A noose among the Mexicans was the symbol for robbery, though more logically belonging to its punishment. In a Californian rock-painting sorrow is represented by a figure from whose eyes drop tears. This could be abbreviated to an eye with tears falling from it, a form recorded by Schoolcraft as existing among the Ojibwa Indians. The symbol is so obvious that it is found with the same value among Egyptian hieroglyphics.

To the more elaborate civilizations of the old world, the development of writing from pictography can be ascribed—the Assyrians (*see* CUNEIFORM), Egyptians (*see* HIEROGLYPHS) and Chinese (*see* CHINESE LANGUAGE). Here more complex notions had to be expressed. The development of the system can be traced through many centuries, and shows a tendency to conventionalize the pictorial symbols employed. Out of conventionalized forms develop (a) syllabaries, (b) alphabets. As regards the latter the historical evolution is traced in the article ALPHABET. The account given under CHINESE LANGUAGE gives a good idea of the development of a syllabary from pictographic writing.

PICKTON, SIR THOMAS (1758–1815), British general, born at Poyston, Pembrokeshire, joined the army in 1773 as an ensign. On the disbandment of the 75th regiment in 1783 Picton quelled a mutiny among the men by his prompt personal action and courage. After living in retirement on his father's estate for nearly 12 years, he went out to the West Indies in 1794. He took part in the capture of St. Lucia (for which he was promoted lieutenant-colonel) and in that of St. Vincent. After the reduction of Trinidad, Abercromby made him governor of the island. He administered the island with such success that the inhabitants petitioned against the retrocession of the island to Spain, and their protest, with Picton's and Abercromby's representations, ensured the retention of Trinidad as a British possession.

In October 1801 he was gazetted brigadier-general. But by this time the rigour of his government, as reported by his enemies, had led to a demand by humanitarians at home for his removal. He was charged with permitting the application of torture under the Spanish law which he had to administer. Colonel William Fullarton (1754–1808) procured the appointment of a commission to govern the island, with Picton as its junior member. Picton resigned, and on his return to England in Dec. 1803 he was arrested by order of the privy council. He was tried in the court of king's bench before Lord Ellenborough in 1806 on one of the charges, on which the court returned a merely technical verdict of guilty, which was superseded in 1808 by a special verdict on retrial. The inhabitants of Trinidad, who had already given him a sword of honour and had petitioned the king not to accept his resignation, subscribed £4,000 toward his legal expenses, which sum Picton contributed in return to the relief of the suffering caused by a widespread fire in Port of Spain.

In 1810, at Wellington's request, he was appointed to command a division in Spain. For the remaining years of the Peninsular War, Picton was one of Wellington's principal subordinates. The commander-in-chief, it is true, never reposed in him the confidence that he gave to Beresford, Hill and Craufurd, but in the resolute, thorough and punctual execution of a well-defined task Picton had no superior in the army. His debut was unfortunate. On the Coa in July 1810 Craufurd's division became involved in an action, and Picton, his nearest neighbour, refused to

support him, as Wellington's direct orders were to avoid an engagement. Details of the incident will be found in Oman, *Peninsular War*, vol. iii. Shortly after this, however, at Busaco, Picton found and used his first great opportunity for distinction. He repulsed the French attack with skill and resolution. After the winter in the lines of Torres Vedras, he added to his reputation and to that of his division at Fuentes d'Onor. In September he was given the local rank of lieutenant-general, and in the same month the division won great glory by its rapid and orderly retirement under severe pressure from the French cavalry at El Bodon. In the first operations of 1812 Picton and Craufurd stormed the two breaches of Ciudad Rodrigo, Craufurd being mortally wounded. At Badajoz, a month later, the successful storming of the fortress was due to Picton's daring self-reliance and penetration in converting the secondary attack on the castle, delivered by his division, into a real one. He was himself wounded in this terrible engagement, but would not leave the ramparts, and the day after, having recently inherited a fortune, he gave every survivor of his command a guinea. His wound and an attack of fever compelled him to return to England to recruit his health, but he reappeared at the front in April 1813. The conduct of his division under his leadership at the battle of Vittoria and in the engagements in the Pyrenees raised his reputation as a resolute and skilful fighting general to a still higher point. Early in 1814 he was offered, but after consulting Wellington declined, the command of the British forces operating on the side of Catalonia. He thus bore his share in the Orthez campaign and in the final victory before Toulouse.

On June 24, 1814, Picton received for the seventh time the thanks of the house of commons for his great services and in 1815 he was made a G.C.B. When Napoleon returned from Elba, Picton, at Wellington's request, accepted a high command in the Anglo-Dutch army. He was severely wounded at Quatre Bras June 16, but concealed his wound and retained command of his troops, and at Waterloo on June 18, while repulsing a serious attack, he was shot through the head by a musket ball. His body was brought home to London and buried in the family vault at St. George's, Hanover Square. A public monument was erected to his memory in St. Paul's cathedral, by order of parliament, and in 1823 another was erected at Carmarthen by subscription, the king contributing 100 guineas to it.

See Robinson's *Life of Sir Thomas Picton* (London, 1836), with which, however, compare Napier's and Oman's histories of the Peninsular War as to controversial points.

PICOU, a seaport, port of entry, and capital of Pictou county, Nova Scotia, Canada, 90 mi. N.E. by N. of Halifax, on the Canadian National railway. Pop. (1951) 4,259. It has several major industries, is the shipping port for the adjacent coal mines and is a busy tourist centre. The Academy was founded in 1818 and played an important part in the early educational history of the province of Nova Scotia.

PICTS, an early people inhabiting Scotland, of uncertain affinities, probably pre-Celtic. They are first mentioned in A.D. 306. In 640 they defeated the Romans and harried the Roman provinces (*see* STRATHCLYDE) until conquered in 846 by Kenneth (q.v.) MacAlpin. Tradition associates the Picts with the great stone monuments.

PICUS, the Latin name of the woodpecker. This bird being sacred to Mars was widely revered in ancient Italy. Occasionally Picus is met with as a minor deity, associated with Faunus, as in the (late and artificial) legend of Picus, Faunus and their capture by Numa, Ovid, *Fast.*, iii, 291 ff. Like many of the minor deities, Picus was rationalized into an ancient king, and a pedigree was made out as follows: Saturn (q.v.), Picus, Faunus (q.v.), Latinus (e.g. Virgil, *Aen.*, vii 45–49). Hence, in various late accounts (a) as Saturn was identified with Cronus, Picus was made equivalent to Zeus; *see* Halliday in *Class. Rev.*, xxxvi, p. 110 (1922). (b) For some unknown reason, Varro (*ap. Augustine, de civit. Dei*, xviii, 15) interpolated into the genealogy, as father of Picus, Stercutius (Sterces, Sterculius, the spirit of manuring fields). (c) Picus is confused with Picumnus, a minor deity worshipped along with Pilumnus the spirit of the pestle (*pila*) (Non-

ius Marcellus, p. 834, Lindsay, citing Macer). (d) Ovid tells a romantic story to the effect that Picus loved a nymph Canens ("the Singer"), repulsed the advances of Circe (*q.v.*) and was turned by her into a woodpecker (*Met.*, xiv, 312 ff.). This seems to be Ovid's own invention; most authors (as Virgil, *Aen.*, vii, 189, Plutarch, *quaest. Rom.* 21) who tell the story of the metamorphosis, say Circe was his wife.

See Carter in Roscher's *Lexikon*, art. "Picus."

PIDDOCK, a bivalve mollusk that bores into chalk cliffs below the low-water line. Piddocks belong to the genus *Pholas*, of the class Lamellibranchia (*q.v.*), and are remarkable in being phosphorescent. (See PHOSPHORESCENCE.) The shell is curiously shaped in adaptation to their boring habit.

PIDGIN ENGLISH. Wherever the English-speaking adventurer has gone among native races in search of trade and profit he has spread Pidgin of one type or another. In the popular mind Pidgin is associated almost exclusively with the English-Chinese jargon spoken on the China coast. This idea was out of date before the middle of the 19th century. Pidgin has almost achieved the status of a world language.

In varying forms, and with varying mixtures of native words, it is current among millions of people in Africa, India, Malaya, the orient, Australia and the islands of the Pacific. In many areas it has developed distinct dialects, some of which are almost completely unintelligible to each other.

The basis of Pidgin is simple, no matter what dialectal form it takes: 300 or 400 English nouns, 40 or 50 verbs, another 100 or so adjectives, pronouns and adverbs, and two or three dozen common native words.

The word Pidgin is a clue to the nature and limitations of this language. "Pidgin" is believed to be a corruption, probably native to the China coast, of the English word "business." It was originally the language of the business or trade that developed between Chinese and Englishmen; other Pidgin dialects have also developed mainly because of trade.

Since the great majority of the original English traders in the Indian and Pacific oceans were ill-educated, since most of their crews were illiterate, foul-mouthed scoundrels from English slums, and since their primary motive was to snatch as much booty as possible for the smallest possible price, they had little time to spare for preserving the integrity of their mother tongue. The jargon they developed was the lowest common denominator of understanding between white and native. It was the maximum concession the Englishman would make to natives who failed to comprehend the English language *in toto* on first hearing.

No effort was made to shape or mould Pidgin into an intelligent language. As a result it is an unruly, bastard jargon, filled with nursery imbecilities, vulgarisms and corruptions. In spite of these handicaps, or perhaps because of them, it extended its sphere of influence, especially in the Pacific. If Pidgin is an unruly, weed-grown jargon, it is above all utilitarian, and its currency among millions of natives is a measure of its utility, not only for contact between white and native, but for contact among the natives themselves.

Pidgin English was the original Basic English. The parallel between Pidgin and Basic is so close that it is impossible to analyze either without being impressed by their remarkable similarity. Basic English, it must be remembered, is a scientific "language" of 850 words, each of which has been carefully selected so that the collective result represents a complete method of saying everything for all everyday purposes. Pidgin, on the other hand, is a haphazard and unscientific "language," usually of considerably less than 600 words and practically never exceeding 1,000. The collective result is identical.

Analysis of these two languages shows additional similarities. Slightly more than 70% of the words in Basic are nouns; in Pidgin about 65% of the words are nouns. About 18% of Basic words are adjectives and adverbs; in Pidgin the figure is about 13%. Verbs in Basic represent only 2% of the total, however; in Pidgin they rise to between 7 and 10%. The remaining 10% in Basic represent grammatical sundries; the remaining 12 to 15% in Pidgin comprise a scanty collection of pronouns and preposi-

tions and words from native dialects. Nearly one-third of the scientifically selected words of Basic are found in unscientific Pidgin. This comparison is interesting because it reveals a natural bondage between these two primary languages.

The Pidgin that developed in the 17th century on the China coast has numerous characteristics which set it apart from other Pidgin dialects. First, there are the Chinese words included, e.g., *amah*, nurse; *chow chow*, food, to eat; *cumshaw*, a present; *taipan*, a boss. Second, there are the English words which have been given peculiar Chinese pronunciation, e.g., *plopa*, proper; *flin*, friend; *Melican*, American. Third, the "-ee" verbal endings, e.g., *loosee*, to lose; *makee*, to make; *tinkee*, to think. The "-ee" suffix also appears in a few other words, e.g., *maskee*, all right, never mind, and *muchee*, much. Chinese Pidgin is easily recognized by these characteristics, in spite of the fact that numerous words found in its vocabulary occur in identical or almost identical form in other Pidgin dialects. *Maskee*, which is probably derived from the Portuguese "masqui," is current throughout Pacific Pidgin. So are *bymby*, by-and-by; *allasame*, similar; *one time*, once; *savvy*, to understand. In Australian Pidgin a car is *eatum wind cart*; the origin is almost certainly in the Malayan Pidgin *wind waggon*, a car.

These similarities should not, however, lead us to suppose that all Pidgin dialects are derived from the jargon used on the China coast. The major Pidgin dialects of the orient, West Africa and the South seas may be regarded as almost completely independent growths, overlapping because many of the words in their vocabularies are basic words and because native imitations of English speech-sounds have led in numerous cases to almost identical corruptions. Here is an example of Chinese Pidgin, given by Charles G. Leland in his *Pidgin-English Sing-Song*, published by Kegan Paul, Trench, Trubner & Co., Ltd.:

Chinaman he makee allo-tim so-fashee China-side. Supposey one piecee fata flog he bull-chilo, supposey that chilo too muchee largo man, all-same olo man—he must catchee floggum, no other ting can do, wat-tim fata nik-ki he. Can makee cly-cly, no more can do. All-same fashion, putlutta floggee yangshee lutta, yeungki floggee nippa, haszeman floggee waifo, mata floggee kaichilos, massa floggee kungpatto, kungpatto floggee shaman.

Translation:

A Chinaman always acts in this way in China. Suppose a father wants to flog his son; if that child is as big as a grown man, the father must catch him to flog him. He can't do anything else if he wishes to strike him. He can make him cry, but nothing more. In the same way an elder brother beats a younger brother, an uncle beats a nephew, a husband beats his wife, a mother beats her daughter, a master beats his steward, and a steward beats a servant.

The difference between this type of Pidgin and the jargon used by natives and whites in the far northern areas of Australia will be immediately evident by reference to this Australian Pidgin version of part of Psalm 23, given by E. Sheppard Sayer, in his *Pidgin English*:

Big Name watchem sheeypsheep. Watchum blackfella. No more belly cry fella hab. Big Name makum camp alonga grass, takum blackfella walkabout longa, no fightum no more hurry wata. Big Boss longa sky makum inside glad; takum walkabout longa too much goodfella.

Translation:

The Lord is my shepherd; I shall not want. He maketh me to lie down in green pastures; he leadeth me beside the still waters. He restoreth my soul: he leadeth me in the path of righteousness for his name's sake.

Not only is the phrasing of this type of Pidgin different, but the words used are of a different type. Whereas the Chinese Pidgin speaker nearly always uses "-ee" as a verbal suffix (an exception is the "-um" ending of "floggum" in the quotation from Leland), the Australian aboriginal and many Pacific natives use an "-em," "-im" or "-um" suffix. This Pacific suffix is a survival of the word "him" used after a verb.

Another Pacific characteristic is the intrusive *fella*, which is indispensable to the Pidgin speaker, although it is practically meaningless. It is a survival of "fellow" used for "one," e.g., *i gudfella*, that's good, *i.e.*, that is a good one.

The differences between Chinese and Australian Pidgin are not accidental. Few, if any, of the original white inhabitants of Aus-

tralia—most of them were convicts from English prisons—had any knowledge of Chinese Pidgin. The Australian jargon was developed independently as a means of contact between white and black. The first immigrants reached Australia in 1788. Within ten years Pidgin was firmly established. From Australia it spread to neighbouring islands. In New Zealand, sealers and whalers attempted to use Pidgin as a means of contact with Maoris in the early years of the 19th century. Pidgin was, however, scorned by the Maoris, who learned the English language with remarkable ease. Whereas Pidgin is used throughout northern Australia, it is practically nonexistent in New Zealand. Many Maoris learned to speak English better than their white compatriots in New Zealand.

Since Pidgin developed on the east coast of Australia at the end of the 18th century, considerably before the Pacific islands were opened up for trade, Australia must be regarded as the primary source of Pacific Pidgin. This Pacific Pidgin is often referred to as Beach-la-mar—a corrupted form of *bêche-de-mer*, a name for the trepang.

The link between Australian and New Guinea Pidgin is naturally close; the New Guinea native's vocabulary includes many words which were first introduced in Australia, among them *spell*, to rest; *sool*, to scold; *plant*, to bury; *bush*, jungle; *go bush*, to run away; *gammon*, not true; *walkabout*, to travel, decamp.

Here is an example of New Guinea Pidgin taken from *Frend Belong Mi*, a monthly magazine in Pidgin established in 1935 by the Roman Catholic mission at Alexishafen for the use of natives:

Wireless i gudfelo samting. Em i samting bilong hariap tru. Wanfelo master i sindaun long haf long liklik mashin, finger bilong em i faitim mashin, nau elektrik bilong mashin i salim tok i go longwe mor. Olrait, longwe mor wanfelo aderfelo master i sindaun long liklik mashin, em i save hirim disfelo tok.

Translation:

Wireless is good. It is swift. A man sits down at a small machine and taps with his finger and electricity sends his message a long way. A long way away another man sits at another machine and understands the message.

The kinship between this New Guinea Pidgin and Australian Pidgin is immediately obvious. The different way in which the words are spelled may be regarded as a little beside the point, because Pidgin is essentially a spoken language. However, several large mission groups have, for many years, been publishing books in Pidgin for native consumption, and the question arises: How far is Pidgin being modified by its reduction to printed forms? It is somewhat unfortunate, not so much for the future of Pidgin English as a language, as for the education of native races, that the mission stations which have entered the printing trade in order to win converts should have made no attempt to adopt a common phonetic standard. They have worked independently, with the result that new "visual" Pidgin dialects were created in areas under mission control.

Here, for instance, is the Lord's Prayer as rendered in print by the Catholic missions at Alexishafen and Vunapope and the Methodist mission at Rabaul:

Alexishafen: Fader bilong mifelo, yu stop long heaven—ol i santuim nem bilong yu—Kingdom bilong yu i kam—Ol i hirim tok bilong yu long ground olsem long heaven. Tude givim mifelo kaikai bilong de—forgivim rong bilong mifelo—olsem mifelo forgivim rong—ol i mekim long mifelo. Yu no bringim mifelo long traum—tekewe samting no gud long mifelo. Amen.

Vunapope: Papa bolong mipela i stap antap—naim bolong ju i tambu—lotu bolong ju i kam—mipela daun olsem ol antap i harim tok bolong ju—ju bringim kaikai tede bolong mipela—ju larim mipela i olsem mipela i larim ol, ol i mekim nogut mipela—ju no bringim mipela klostu long rot i nogut—ju lusim ol samting nogut i raus long mipela. Amen.

Rabaul: Papa bilong mi fela, iu stop an top alog peles bilong iu, i qud mi fela sigsig out tru alog nem bilong iu; i moa beta ol a fasin bilong iu i stop alog oltuqeta peles. I qud mi fela mekim tru ol a lo bilong iu, ol a sem oltuqeta man i savi mekim alog peles bilong iu. I qud iu givim mi fela kaikai inafim mi fela alog tude. I qud iu no mekim koros alog mi fela alog ol a fasin no qud mi fela mekim, ol a sem mi fela no qat koros alog ol a man i savi korosim mi fela. Iu no bringim mi fela alog ol a samting no qud; i moa beta iu luk outim mi fela so mi fela no ken mekim ol a fasin no qud. Bikos ol a lo, na oltuqeta strog, na oltuqeta samting i qud i bilong iu, na i no ken finis. Amen.

These confusing variations in phonetic form and translation occur throughout the books printed by the missions.

The Alexishafen mission has published more Pidgin books than other missions. It has printed Pidgin Bibles, song books, stories of the Gospels, prayer books, a Pidgin vocabulary and a *Primer* used for teaching young natives in mission schools. The monthly magazine, *Frend Belong Mi* (mentioned above), is mainly religious in nature, but contains crossword puzzles, jokes, fairy tales, problems, astronomy, notes on animals and insects, all in Pidgin.

The government administration of New Guinea refused to use Pidgin in any of its native schools and has issued no official publications in Pidgin. In native schools conducted by the administration pure English is taught, and the medium used is the native dialect of the locality in which the school is situated.

It must be regarded as unfortunate that New Guinea administration attempts to weed out Pidgin did not receive mission support. The difficulty of weaning natives from Pidgin is sufficient without being increased. This was well realized by German traders in the New Guinea islands in the closing quarter of the 19th century. They found that Pidgin English was so firmly rooted that the natives refused to speak German. Baron von Hesse-Wartegg urged that "Pidgin nonsense" should be replaced "by a sensible German language." "There is yet time to eradicate Pidgin English," he added. "Another 10 years without such an effort will see such a deep establishment of it that this might be impossible; and in another 50 years the German reich will possess here a protectorate whose population of missionaries will speak only English. For the world standing of Germany this would certainly be sad and shameful."

By the time of World War II, all that remained of German attempts to weed out Pidgin English was a handful of German words absorbed into Pidgin text; among them *raus*, shift, go away (from *heraus*); *bung* or *boong*, a market; *mark*, a shilling or other silver coin; *puss-puss*, love (from German dialectal *pussi*, a kiss).

The original French settlers of New Caledonia found similar difficulties. Long before French immigrants arrived, Pidgin English had been spread among the New Caledonian natives. Many traces of that Pidgin remain incorporated in the French speech used in New Caledonia and the New Hebrides. A form of Pidgin French is also current.

Among well-known picturesque phrases in Pidgin are: *bullamakau*, beef, meat in general, whence *bullamakau banana*, a sausage; *haus moni gammon*, banknotes, as distinct from *haus moni tru*, coins; *grass belong face*, whiskers; *dog belong Sydney*, a goat; *basket belong trouser*, a pocket; *lamp belong Jesus*, the sun; *ticky-ticky wata*, oil; *paper talk* (or, in Australian Pidgin, *paper yabber*), a letter.

In World War II the importance of soldiers in contact with natives in southwest Pacific islands knowing Pidgin was realized by both U.S. and Australian army authorities. A special handbook was issued to servicemen on tropical duty. Here are two examples from the book, showing how Pidgin went to war:

Yufela yu lookim barid all Japan i sit down long im long fight? Is there barbed wire in front of the Jap trenches?

Yufela yu stand fast. Yu no can walkabout. Suppose yufela walkabout me killim yu long musket. Don't move or I'll shoot.

(S. J. BR.)

PIECE-OF-EIGHT, an obsolete Spanish coin, properly the *piastre* or *peso*, commonly also called a dollar, coined of silver, and divided into eight *reales*, whence "piece-of-eight." Its value was four shillings. In 1797, when the Bank of England suspended payment, millions of these coins were put into British circulation, countermarked with a small oval bust of George III. The piece-of-eight was current in the Spanish-American colonies.

PIECE-WORK, a term used to describe the method of industrial remuneration in which the worker is paid by the piece or job. In practice, where piece-work is arranged in trades that are organized, the payment per unit of work is arranged by negotiation between the employers and employed, as for example, in the English cotton industry. Very often the agreements arrived at

are extremely complicated, with various percentage variations upon a basic rate, so that the expression of piece-rate becomes very difficult for one outside the industry to understand. Agreements as to piece-work are often subject to a minimum wage arrangement. See *WAGES: Trends in Wage Levels in the United States*.

PIEDMONT is a territorial division of north Italy, enclosed on all sides except toward the Lombard plain by the vast semicircle of the Pennine, Graian, Cottian, Maritime and Ligurian Alps. In 1859 it was divided into the four provinces of Alessandria, Cuneo, Novara and Torino (Turin) to which Aosta and Vercelli were added in 1927 and later Asti. It has an area of 11,332 sq.mi. The people are chiefly engaged in agriculture—which is helped by irrigation.

In 1938, the products were:

Crop	Acres	Tons
Wheat	753,350	616,847
Rye	108,186	66,028
Oats	40,261	30,313
Rice	180,804	415,236
Maize	370,000	799,388
Beans	106,951	35,384
Sugar beets	7,103	51,367
Hemp	2,223	1,102
Garden produce	10,760	81,350
Potatoes	84,474	374,341
Forage	2,482,103	3,588,427
Vines	550,310	106,674,915 (wine-gallons)

Many are also occupied in the reeling and throwing of silk and in the manufacture of cotton (no fewer than 50,000 workers, of whom 37,000 are women), woollens and clothing; there are also considerable manufactures at Turin, Savigliano, etc. The Piedmontese dialect has been rather strongly influenced by French.

The total population of Piedmont was in 1931, 3,497,799, in 1951, 3,513,111. There are numerous summer resorts in the Alpine valleys.

The chief railway centres are Turin, communicating with the Mont Cenis line and with the Riviera by the railway over the Col di Tenda. The communications with Liguria are difficult owing to the approach of the mountains to the coast, but the electrification of the lines from Genoa to Turin and Milan greatly improved the travelling facilities of this region.

Piedmont (Ital. *Piemonte*; Low Lat. *Pedemons* and *Pedemonium*), in Roman times until 49 B.C. formed a part of Gallia Transpadana, and in Augustus' division of Italy formed with what was later known as Lombardy the 11th region. It formed part of the Lombard kingdom, and it was not till about A.D. 1000 that the house of Savoy (*q.v.*) arose.

PIEDMONT, a residential city of California, U.S.A., on the heights facing San Francisco bay and the Golden Gate. It is almost exclusively a community of homes. The population was 10,132 in 1950, 9,866 in 1940 by the federal census.

PIEDMONT REGION. A term of special application in the U.S. to the low plateau which lies just east of the Appalachians, especially in Pennsylvania, Virginia and the Carolinas.

PIEDRAS NEGRAS, formerly Ciudad Porfirio Díaz, a northern frontier city of Mexico in the state of Coahuila, 840 mi. N. by W. of Mexico City, on the Río Grande del Norte, 720 ft. above sea level, opposite the city of Eagle Pass, Tex. The population in 1950 was 27,578. An international bridge connects the two cities, and the Mexican National railways have a northern terminus at this point.

The city has an important transfer trade with the U.S. and is the centre of a fertile district devoted to agriculture and stock raising. Coal is found in the vicinity; silver, zinc and copper are also mined.

The Mexican government maintains a customhouse and military post there. The town was founded in 1849.

PIENZA, a town of Tuscany, Italy, in the province of Siena 9 mi. W. of the town of Montepulciano by road, 1,611 ft. above sea level. Population (1951) 4,768 (commune). The

place was originally called Corsignano and owes its present name to Aeneas Silvius Piccolomini, Pope Pius II. (*q.v.*) who was born here in 1405. The buildings which he caused to be erected by Bernardo Rossellino in 1460–1463 form a noble group of early Renaissance architecture round the Piazza del Duomo. The latter retains Gothic details in the interior, but the facade is simple Renaissance work. The other three sides are occupied by the episcopal and municipal palaces, and the Palazzo Piccolomini; the last, resembling the Palazzo Rucellai at Florence, is the finest, and is well furnished: in front of it is a beautiful fountain, and opposite it the fine Palazzo Ammannati. The canons' house contains a museum with some fine ecclesiastical vestments including an excellent 13th century cope of English origin, and enamels.

PIER. In architecture (*q.v.*) it usually denotes a vertical support in masonry, brickwork or concrete which carries an arch or superstructure. In this sense it is applied both to those portions of a structure which are visible above ground and to isolated or detached supports underground described as foundation piers. The term is sometimes applied to the solid parts of a wall between windows or voids, and also to the isolated masses of brickwork, masonry or concrete to which gates are hung.

Bridge Piers.—In the construction of bridges (*q.v.*) and viaducts, *pier* denotes the solid structure upon which the bridge superstructure (including arches) is supported. Occasionally in the case of high piers supporting viaducts and bridge superstructures the upper portions are constructed of open-braced iron- or steel-work.

Foundation piers for bridges are formed of solid masonry, brickwork or concrete and, sometimes, reinforced-concrete is employed for the purpose. In places where timber is abundant, as in some parts of the United States and Canada, wooden cribs filled with rubble stone or concrete have been used for raising the foundations of piers out of water.

Special provisions must be made for the foundations of piers where the ground is soft for some depth, or loose water-bearing strata are encountered, and especially where the piers of large

THREE TYPES OF PIER USED IN ARCHITECTURE

bridges crossing rivers have to be constructed under water. Among the means employed in these situations are steel and iron cylinders, wells, caissons, bearing piles or some form of cofferdam within which the foundations may be constructed. (See *CAISSON*, *FOUNDATIONS*, *COFFERDAM*.)

Piles are sometimes employed to provide both the foundations and the piers carrying a structure of viaduct character. Thus screw piles, having wide bearing-blades of cast-iron in the form of

a screw-thread turned about a central shaft or column of cast-iron or steel, are sometimes sunk through soft strata till they reach a firm bed, or one sufficiently consolidated by the superincumbent layers to enable it to support the weight imposed on the broad blades. Hollow, cast iron, cylindrical piles with a broad circular disc at the bottom to increase their bearing surface, have also been used for piers founded in sandy or silty strata of considerable thickness. They are sunk by hydraulic jetting, *i.e.*, the scouring away of the soft material from under the disc by means of a jet of water emitted under high pressure from a pipe lowered within the pile. Water jets are also employed to facilitate the sinking of screw and other forms of piles. (*See FOUNDATIONS.*)

Harbour Piers.—The term pier is often applied to works sheltering harbours such as the Tynemouth piers which are strictly breakwaters (*q.v.*). Landing stages also, whether solid or open, have for a long time been called piers, as the Admiralty pier and the Prince of Wales' pier at Dover, the former essentially a breakwater with provision for berthing vessels and landing passengers on its sheltered side. The jetties (*q.v.*) thrown out from the shore to protect the entrance to a river harbour are also sometimes described as piers. In North America the term is commonly employed for a wharf structure that projects into a river, fairway or harbour.

Promenade Piers.—Open promenade piers form a common feature at seaside resorts. Promenade piers are usually supported on open pile work of timber, cast iron or steel, but in recent years, reinforced concrete has been frequently employed both for the pile supports and superstructure. The open construction exposes little surface to waves or storms and does not interfere with the drift of shingle and sand along the coast. It is essential that the beams or girders carrying the deck of a promenade pier should be at an elevation well above the level of the crest of the highest wave. Timber piles are best suited for withstanding the shocks of vessels at landing stages, at which places they are generally used. In the case of reinforced-concrete landing stages, a falsework of timber is sometimes constructed in front of the main structure for this purpose. Screw piles are frequently used for promenade piers on sandy foreshores.

The pioneer of promenade piers in England was the old oak pier at Brighton, erected in 1822-3. It was founded on chain piles, was 1,136 ft. long and was destroyed by a gale in Dec. 1896. The length of promenade piers depends mainly on the distance from the shore at which sufficient depth is reached for steamers. Thus piers at Southend (Essex) and Southport (Lancs.) have been constructed across the wide sands in the estuaries of the Thames and Ribble respectively; the former over 1½ m., the latter nearly a mile in length.

Works on bridge and other foundations are noted at the end of the article CAISSON.

(N. G. G.)

In Architecture.—A pier in architecture is a vertical support carrying arches, a vault, a floor or a roof; especially one rectangular in plan; also, in mediæval work, any support between the nave and aisles of a church. During the late Roman imperial period, pier design was carefully studied and in connection with such buildings as the basilicas, cross-shaped and other compound piers were developed to carry the cross arches and the groins or intersections of the vaulting. With the increasing use of vaulting for church naves and aisles, during the 11th and 12th centuries, pier design was still further developed. Although in England Norman piers are frequently great round columns, on the continent of Europe piers became common in which each arch or vaulting rib above was carried by a separate member of the pier. The earliest logical expression of this idea is found in Italian Lombard work, where a square pier has frequently an engaged column attached to each face; the one on the nave side carrying the cross-rib of the nave vault, that on the aisle side carrying the aisle vault cross-rib, and those on the other two sides carrying the pier arches between nave and aisles.

During the later Romanesque, pier plans were further complicated by the addition of smaller members to carry the subsidiary mouldings of the arches above, and larger members to carry the diagonal vaulting ribs. (*See* BYZANTINE AND ROMANESQUE ARCHI-

TECTURE.) During the 13th and 14th centuries the piers of French Gothic churches were kept comparatively simple in plan, with great importance given to the capital at the level of the spring of the pier arch. Often it took the shape of a circular column with a few, large, simple attached vaulting shafts, as in Rheims cathedral (*c.* 1240). Toward the end of the 14th century, perhaps due to English influence, the column idea disappeared and was replaced by the more logical plan in which the pier was elaborately membered, not only by the additional development of vaulting shafts, but by breaking up the edges with projecting mouldings under the mouldings of the arches. Capitals became of less importance and vaulting shafts were carried unbroken through from floor to vault spring, capitals being placed merely on the separate mouldings of each arch or rib.

During the Flamboyant period this development was carried to its logical extreme; capitals were omitted entirely, and the pier plan became the combination of the various arch and vault rib mouldings continued down to the floor. Against this complexity a reaction was inevitable, and the other type of French Flamboyant pier developed, with smooth surface, either circular or wavy in plan, with the various vault rib and arch mouldings carried by the pier merely dying into it at their intersections. In England, during the Early English period, although circular piers are occasionally found, they were more frequently surrounded by entirely independent colonnettes, often of black Purbeck marble, which act as vaulting shafts and are tied to the body of the pier only at intervals by horizontal through stones with moulded edges. During the Decorated period attached shafts continued in use but the surfaces of the central core appearing between them were often richly moulded, and, in some cases, detached shafts disappeared entirely and the pier became a solid mass with surfaces lavishly moulded with strong projecting high lights and deeply cut shadows.

In the late Decorated period mouldings of the pier were sometimes the same as those of the arch above and capitals were omitted. This arrangement became much more frequent during the Perpendicular period. Pier-moulding profiles were softened and flattened like other mouldings of the period. (*See* GOTHIC ARCHITECTURE.) With the coming of the Renaissance pier design was much simplified, returning to the generally cross-shaped or twelve-cornered systems found in late Roman work, with all the projecting members treated either as classic imposts, engaged columns or pilasters.

Technically, the word pier is also applied to the solid portions of a wall between windows or other openings; and to the vertical posts at gateways, to which the gates are hung. The word pier is used of structures of timber or masonry projecting from a quay or sea wall and used either for loading and unloading ships, or in the case of summer resorts, for furnishing promenade space into the water. In America the word is loosely used synonymously with dock or landing stage.

PIERCE, FRANKLIN (1804-1869), fourteenth president of the United States, was born at Hillsboro, New Hampshire, Nov. 23, 1804. His father, Benjamin Pierce (1757-1839), served in the American army throughout the Revolutionary War, was a Democratic member of the New Hampshire house of representatives from 1789 to 1801, and was governor of the State in 1827. The son was prepared for college at Hancock, Franconia and Exeter academies and entered Bowdoin in 1820, where he formed a lifelong friendship with Nathaniel Hawthorne. After his graduation in 1824 he studied law and was admitted to the bar in 1827.

Entry into Politics.—Entering politics as a Democrat he became a member of the New Hampshire house of representatives in 1829, and was speaker of that body in 1831 and 1832. The following year he entered the national house of representatives. While he rarely spoke from the floor, he was an influential member of several committees, including the judiciary committee. A friend of President Jackson he supported administration policies. He adhered to a strict construction of the Federal Constitution, defended the Maysville veto, opposed the recharter of the bank of the United States, opposed appropriations to the U. S. military academy and favoured a volunteer army. During

his first term in Congress he married Jane Means Appleton, daughter of the president of Bowdoin college. In 1837 he entered the U.S. Senate. Being its youngest member, he was overshadowed by a galaxy of older and more prominent men such as Benton, Clay and Webster. Before his term expired he resigned his seat (1842) and returned to the practice of law at Concord, N.H., where he became Federal district attorney. In 1845 he was offered the Democratic nomination for governor of New Hampshire, also an appointment to fill an unexpired term in the U.S. Senate, and the next year the position of attorney-general in Polk's cabinet; but he rejected them all, declaring that he had permanently retired from political life.

Service in Mexican War.—Shortly after the outbreak of the war with Mexico in 1846 Pierce enlisted as a private at Concord, but soon became colonel of the 9th Regiment, and later a brigadier-general of volunteers. He was with Gen. Scott in the advance toward Mexico City. During the battle of Contreras he was thrown from his horse and received painful injuries. Despite the advice of Scott to the contrary he insisted on continuing the fight the next day and in the course of the battle he fainted. This fact, variously interpreted, was used both for and against him when he was later a candidate for the presidency. At the close of the war he returned to his law practice.

Election to Presidency.—Pierce became the Democratic nominee for president in 1852 "as a dark horse." Those in the foreground were Lewis Cass, Stephen A. Douglas and James Buchanan, but none of these proved to be available because of factional rivalries. A few politicians, foreseeing a deadlock, had prepared Pierce for the place. At the convention in Baltimore in June his name was first brought forward by the Virginia delegation on the 35th ballot, and on the 49th ballot he received an almost unanimous vote. Both the Democrats and the Whigs were too badly split for any real issues to appear in the campaign. The chief question in the public mind was the finality of the Compromise of 1850, and while both parties declared themselves in favour of it the Democrats were more thoroughly united in its support. As a result Pierce swept the country in the November election, receiving 254 electoral votes against 42 for his opponent, Gen. Winfield Scott.

Presidential Administration.—The youngest man to have been elevated to the presidency, Pierce was handsome, genial and possessed of a certain brilliance, which however was not profound. The Eastern element of the Democratic party which he directly represented was inclined for the sake of harmony and prosperity to oppose anti-slavery agitation and generally to placate Southern opinion. It was hence pro-Southern as a matter not only of political strategy but also of business expediency. Thus in the selection of his cabinet, as in both domestic and foreign policies of his administration, Pierce represented a coalition of Southern planters and Eastern business men. His cabinet included William L. Marcy of New York, secretary of state; Jefferson Davis of Mississippi, secretary of war; James Guthrie of Kentucky, secretary of the treasury; James C. Dobbin of North Carolina, secretary of the navy; Robert McClelland of Michigan, secretary of the interior; James Campbell of Pennsylvania, postmaster-general; and Caleb Cushing of Massachusetts, attorney-general. In his inaugural address Pierce interpreted his election as a popular mandate to maintain the Compromise of 1850 and bury the slavery controversy. He also forecast an aggressive, but honourable, foreign policy; he would "not be controlled by any timid forebodings of evil from expansion." In fact "the acquisition of certain possessions" (doubtless referring to Cuba in particular) was deemed essential to the country's safety and commerce.

Foreign Policy.—In accordance with the declarations of the inaugural Pierre Soulé, who had openly advocated the annexation of Cuba by means other than purchase if necessary, was appointed minister to Spain. When the Spanish Government showed its unwillingness to sell the island, Soulé, at the suggestion of secretary of State Marcy, held a conference with James Buchanan, minister to Great Britain, and John Y. Mason, minister to France, at Ostend, Belgium, as a result of which they issued the famous Ostend Manifesto. This was to the effect that if the

United States were unable to obtain Cuba peacefully, "by every law, human and divine, we shall be justified in wresting it from Spain if we possess the power." In the storm of controversy which followed, the administration disclaimed responsibility for the document and recalled Soulé. The following year William Walker conducted a notorious filibustering expedition into Central America with the purpose of establishing a pro-slavery government to be brought under the control of the United States. He established himself as military dictator, then as president, of Nicaragua, and his regime was recognized by the Pierce administration. More fruitful of permanent results was the expedition sent out under Commodore Perry to Japan (1853) to induce her to open her doors to American trade. Lured by Yankee ingenuity and frightened by Western guns, she responded, and the result was the opening up of Japan. In the Kozsza affair (1853) the government vigorously asserted the protection which it would offer those in the process of becoming its naturalized citizens. The administration also effected a reorganization of the diplomatic and consular service and the creation of the U.S. court of claims.

Domestic Policy.—Among the domestic policies of the Pierce administration were preparations for a transcontinental railroad and the opening up of the Northwest for settlement. It was in order to open the way for a southerly route to California through the lowest mountain passes that the Gadsden Purchase of 50,000 sq.m. of territory was acquired from Mexico in 1853 at a cost of \$10,000,000. It was mainly to stimulate migration to the Northwest and facilitate the project of a central route to the Pacific that the Kansas-Nebraska bill was enacted in 1854, receiving the President's sanction. This opened two new territories for settlement with the slavery question to be settled in each by popular sovereignty. Thus the dread conflict was reawakened with the venom of incipient civil war. Pierce's administrative policies with reference to "bleeding Kansas" were pro-Southern. He thus lost much of his former support at the North and made himself unavailable as a candidate for a second term.

Save for a three years' tour in Europe, he lived at Concord, N.H., where he died on Oct. 8, 1869.

PIERO DI COSIMO (1462-1521), the name by which the Florentine painter Pietro di Lorenzo is generally known. He was born in Florence in 1462, and worked in the *bottega* of Cosimo Rosselli (from whom he derived his popular name). He had the gift of a fertile fantastic imagination, which, as a result of his journey to Rome in 1482 with Rosselli, became directed towards the myths of classic antiquity. In Rome he assisted his master with the frescoes in the Sistine chapel. He proves himself a true child of the Renaissance in such pictures as the "Death of Procris," at the National Gallery, the "Mars and Venus," at the Berlin Gallery, the "Perseus and Andromeda" series, at the Uffizi in Florence, and the "Hylas and the Nymphs," of the late Benson collection. The "Immaculate Conception," at the Uffizi, and the "Holy Family," at Dresden, are good examples of his religious pictures. Piero was distinguished for his landscapes and their cheerful accessories. The only known portraits that can be definitely ascribed to him are, at the National Gallery, the so-called "Bella Simonetta," at Chantilly, the portraits of Giuliano di San Gallo and his father, at The Hague, and a head of a youth, at Dulwich. Vasari related that Piero excelled in designing pageants and triumphal processions for the pleasure-loving youths of Florence. Piero di Cosimo exercised considerable influence upon his fellow pupils Albertinelli and Bartolommeo della Porta and was the master of Andrea del Sarto. Examples of his work are also to be found at the Louvre in Paris, the Liechtenstein collec-

tion in Vienna, the Borghese and Corsini Galleries in Rome, the Berlin Museum, the Spedale degli Innocenti in Florence, and in the collections of Burke in London and Cornwallis West in Newlands Manor.

PIERRE, the capital city of South Dakota, U.S., and county seat of Hughes county; in the centre of the state, on the east bank of the Missouri river opposite the mouth of Bad river, at an altitude (at the state capitol) of 1,496 ft. It is on federal highways 14 and 83; and is served by the Chicago and North Western railway and Western Air Lines. Pop. (1950) 5,715; (1940) 4,322. Four miles north of the city is a monument marking the geographical centre of the state and the approximate centre of North America. The state capitol (erected 1905–10) is a beautiful building. A new state building across from the capitol was completed in 1950. Near the capitol is an artificial lake, fed from an artesian well by water which never freezes, where swans, geese and wild ducks live the year around. The city owns more than a mile of river frontage, and its parks include a wooded island of 1,000 ac. Artesian wells supply the city not only with water but also with natural gas of high heating content. Pierre is the seat of a government Indian school.

The state historical museum (in the capitol) has many interesting relics, including a leaden plate, buried in 1743 by Pierre de la Verendrye on a hill across the river (within the present city of Fort Pierre) to claim the country for France, and discovered by high school children in 1913. Pierre is an important shipping point and centre of wholesale and jobbing interests. It has railroad shops, granite works and other manufacturing industries. The first permanent settlement by white men in South Dakota was made in 1817 by Joseph la Framboise, a fur trader, just below the mouth of Bad river. He called his post Fort Teton. In 1822 Fort Tecumseh was built 2 mi. upstream; and in 1832, when its site was washed into the river, Fort Pierre Chouteau was erected to take its place, a mile farther upstream and a little back from the river. It was named after Pierre Chouteau, Jr. (1789–1865), who had in 1804 succeeded his father in the Missouri Fur company, and for 20 years Fort Pierre (as it soon came to be called) was the chief fur-trading depot of the upper Missouri country. In 1855 the United States bought the building and other property of the post and laid out around them a military reservation of 270 sq. mi. (abandoned in 1857) which was the headquarters of operations against the Sioux and the scene of a council with their chiefs. In the early days steamboats plied regularly on the Missouri river as far as Fort Benton (Montana) 1,000 mi. above Pierre. The first sermon in South Dakota was preached in 1840 by the Rev. Stephen R. Riggs, a missionary to the Dakota Indians, on a spot near the free wagon bridge across the Missouri which bears his name. The city was platted in 1880, incorporated as a village in 1883 and chartered as a city in 1900. One of the few surviving herds of buffalo in the United States is quartered in the river brakes 4 mi. north of Fort Pierre.

PIERREFONDS, a town of northern France, in the department of Oise, 9 mi. S.E. of Compiègne by road. Pop. (1954) 1,370. Pierrefonds has an 11th to 16th century church, and its mineral springs are in some repute. The famous château was begun in the late 14th century by Louis d'Orléans, to whom the domain was given by Charles VI, and finished early in the 15th century. It was later held by the Burgundians, the English and the adherents of the League, from whom it passed to Henry IV. It was dismantled in 1622. The ruins, bought by Napoleon I, were faithfully restored, by order of Napoleon III, in 1858–95, under the direction, first of Viollet-le-Duc and afterwards of E. Boeswillwald. The building is rectangular in shape, with a tower at each corner and at the centre of each of the walls. A lofty keep defends the principal entrances, on the southwest.

PIERROT [Ital. *Pedrolino*], the name given to the leading character in the French pantomime plays since the 18th century; transferred from the Italian stage, and revived especially in recent times. He is always in white, both face and costume, with a loose and daintily clownish garb, and is represented as of a

frankish disposition. Modern pierrot plays have converted the pierrot into a romantic and pathetic figure.

PIETAS, in Roman mythology, the personification of the sense of duty towards God and man and towards the fatherland. According to legend, a young woman in humble circumstances, whose father (or mother) was lying in prison under sentence of death, without food, managed to gain admittance, and fed her parent with milk from her breast. To commemorate her filial affection, a temple was dedicated (181 B.C.) by Manius Acilius Glabrio to Pietas in the Forum Holitorium at Rome, on the spot where the young woman had formerly lived. The temple was probably originally vowed by the elder Glabrio out of gratitude for the *pietas* shown during the engagement by his son, who may have saved his life, as did the elder Africanus that of his father at the battle of Ticinus (Livy xxi. 46); the legend of the young woman (borrowed from the Greek story of Mycon and Pero, Val. Max. v. 4; ext. 1) was then connected with the temple by the identification of its site with that of the prison. Pietas is shown on coins as a matron throwing incense on an altar, her attribute being a stork.

Typical examples of "piety" are Aeneas, and Antoninus Pius, who founded games at Puteoli in honour of Hadrian.

PIETERMARITZBURG, the capital of Natal province, Union of South Africa, lies on the Umsundusi river in hilly country, 2,218 ft. above sea level and 54 mi. N.W. of Durban by road and 73 mi. by rail. Pop. (1951) 73,273, including 31,496 Europeans, 22,355 Africans, 16,011 Asians and 3,411 coloured.

Founded by the Boers in 1839 after a victory over the Zulus, Pietermaritzburg was named in honour of the dead leaders, Pieter (Piet) Retief and Gert Maritz. It was believed to be free from cattle sickness and for this reason was chosen as a Trekker capital in preference to Port Natal. The first houses of the European settlement were built in 1839 and Pietermaritzburg was proclaimed a city when the first bishop was appointed to the new see of Natal in 1853. Three years later it became the colonial capital of Natal.

The main town lies between the Umsundusi river and the Dorpspruit, but suburbs have spread to two ridges on the farther side of the river to the southeast, and also to the slopes of an escarpment which rises over 1,500 ft. to the northwest. On the low ground between the ridges across the river are Indian dwellings, public parks and sports grounds and some cultivation. To the west of the town are the botanical gardens. Among many striking buildings in the city are the Anglican and Roman Catholic cathedrals, the Voortrekkers' museum in what was formerly a Dutch church, an art gallery and the Natal museum which houses an excellent collection of South African fauna. The town hall has a fine organ and a good selection of pictures. There are a teachers' training college, a technical institute and a university college affiliated with the University of South Africa, as well as many schools.

The valleys among the hills are cultivated and Pietermaritzburg is an agricultural centre as well as having several industries. Manufactures include building materials, shoes and metal and rubber products. Iron is mined in the region. There are rail communications with Durban, Johannesburg and other cities in the Union.

PIETERSBURG, chief town of the Pietersburg district of the Transvaal, 177 mi. by rail N.N.E. of Pretoria; altitude, 4,269 ft. Pop. (1951) 7,644 whites, 11,766 natives, 692 Asiatics and 239 "coloured"; total 20,341. The surrounding country contains minerals. To the east are the Klein Letaba and other low country gold fields; to the west are the Waterberg gold fields. Asbestos, tin and corundum also occur, the latter being exported in fair quantity. Cereals, tobacco, cotton and peanuts are cultivated and toward the east citrus estates have developed.

PIETERS HILL, 10 mi. S.S.E. of Ladysmith, gave its name to the fourth and finally successful British attempt to relieve Ladysmith at the end of Feb. 1900 (see *LADYSMITH* and *SOUTH AFRICAN WAR*, 1899–1902). Sir Redvers Buller, having tried a frontal attack and two attacks on the right of the Boer lines, resolved to assail their left, and operations opened with the storming of their positions on the south bank of the Tugela east of Colenso, which fell into British hands after six days of methodical

fighting. Thereafter, Buller drew back the bulk of his force to the north bank, its next objective being the group of hills immediately north of Colenso. On Feb. 27, the British right wing captured Pieters hill, the northern buttress of the ridge, and next day Buller's cavalry entered Ladysmith, which had stood a four months' siege.

PIETISM, a movement in the Lutheran Church, which arose toward the end of the 17th and continued during the first half of the following century. The name of Pietists was given to the adherents of the movement as a term of ridicule, like that of "Methodists" somewhat later in England. The Lutheran Church had continued Philipp Melancthon's attempt to construct the evangelical faith as a doctrinal system; and it appeared to many faithful adherents to have become a creed-bound theological and sacramentarian institution, where the dogmatic formularies of the church had usurped the position which Martin Luther himself had assigned to the Bible alone. The influence of the Reformed Church (*q.v.*) on the other hand, in spite of the predestinarianism of John Calvin, made less for doctrine than the practical formation of Christian life. The Presbyterian constitution gave the people a share in church life which the Lutherans lacked, but it involved a dogmatic legalism which imperilled Christian freedom and fostered self-righteousness.

The direct originator of the movement for the revival of a practical and devout Christianity was Philipp Jakob Spener, who combined the Lutheran emphasis on Biblical doctrine with the Reformed tendency to vigorous Christian life. Born at Rappoltsweiler in Alsace on Jan. 13, 1635, trained by a devout godmother, who used books of devotion like Johann Arndt's *True Christianity*, accustomed to hear the sermons of a pastor who preached the Bible more than the Lutheran creeds, Spener was early convinced of the necessity of a moral and religious reformation of the German church. He studied theology, with a view to the Christian ministry, at Strasbourg and entered upon his first pastoral charge at Frankfurt-on-Main, profoundly impressed with a sense of the danger of the Christian life being sacrificed to zeal for rigid orthodoxy. Pietism, as a distinct movement in the German church, was then originated by Spener by religious meetings at his house (*collegia pietatis*), at which he repeated his sermons, expounded passages of the New Testament and induced those present to join in conversation on religious questions that arose. They gave rise to the name "Pietists." In 1675 Spener published his *Pia desideria*, or *Earnest Desires for a Reform of the True Evangelical Church*. In this publication he made six proposals as the best means of restoring the life of the church: (1) the earnest and thorough study of the Bible in private meetings, *ecclesiolae in ecclesia*; (2) the Christian priesthood being universal, the laity should share in the spiritual government of the church; (3) a knowledge of Christianity must be attended by the practice of it as its indispensable sign and supplement; (4) instead of merely didactic, and often bitter, attacks on the heterodox and unbelievers, a sympathetic and kindly treatment of them; (5) a reorganization of the theological training of the universities, giving more prominence to the devotional life, and (6) a different style of preaching, namely, in the place of pleasing rhetoric, the implanting of Christianity in the inner or new man, the soul of which is faith, and its effects the fruits of life. This work produced a great impression throughout Germany, and although large numbers of the orthodox Lutheran theologians and pastors were deeply offended by Spener's book, its complaints and its demands were both too well justified to admit of their being point-blank denied. A large number of pastors at once practically adopted Spener's proposals. In Paul Gerhardt the movement found a singer whose hymns are genuine folk poetry. In 1686 Spener accepted an appointment to the court chaplaincy at Dresden, which opened to him a wider though more difficult sphere of labour. One of his most enthusiastic disciples was August Hermann Francke, who had founded the famous orphanage at Halle, and with the aid of Christian Thomasius and Spener founded the new university there. The theological chairs were filled in conformity with Spener's proposals. Spener died in 1705; but the movement, guided by Francke, spread over middle and north Germany. One of its greatest achievements was the organization of the Moravian Church in 1727 by Count von Zinzendorf, Spener's godson and a pupil in the Halle orphanage.

Pietism, of course, had its weaknesses. Many Pietists maintained that the new birth must always be preceded by agonies of repentance,

and that only a regenerated theologian could teach theology, while the whole school shunned all common worldly amusements, such as dancing, the theatre and public games. There thus arose a new form of justification by works. As a distinct movement Pietism had run its course before the middle of the 18th century; by its very individualism it had helped to prepare the way for another great movement, the Enlightenment (*q.v.*).

PIETRO DELLA VIGNA or PIER DELLE VIGNE

[PETRUS DE VINEAS or DE VINEIS] (c. 1190–1249), chancellor and secretary to the emperor Frederick II, born at Capua in humble circumstances, studied law at Padua. He became secretary to Frederick II, who made him *judex magnae curiae*, councillor, governor of Apulia, prothonotary and chancellor. The emperor, "of whose heart he held the keys," as Dante says, sent him to Rome in 1232 and 1237 to negotiate with the pope, to Padua in 1239 to induce the citizens to accept imperial protection, to England in 1234–35 to arrange a marriage between Frederick and Isabella, sister of King Henry III. He proved a skilful and trustworthy diplomat, and he persistently defended the emperor against his traducers and against the pope's menaces. At the Council of Lyons Pietro della Vigna entrusted the defense of his master to the jurist Taddeo di Suessa, who failed to prevent his condemnation. Frederick had his chancellor imprisoned and blinded without giving him a chance to rebut his accusers. He is said to have committed suicide in his prison at Pisa in 1249. His tragic fate gave rise to many legends.

Pietro della Vigna wrote verse in the vernacular tongue, of which two *canzoni* and a sonnet are extant. His letters (*Epistolarum libri vi.*, 2 vols., Basel, 1740), are of historical value. A collection of the laws of Sicily, a *Tractatus de potestate imperiali*, and another treatise, "On Consolation," in the style of Boethius, are also attributed to him.

PIG, a common name given to the domestic swine of any age. Hog is used collectively with much the same meaning as pig, hog being generally used in the U.S. and pig usually referring to the young animal. Swine is applied to any hoofed animal of the family Suidae, in a broad sense including the peccaries (*see* SWINE).

The origin of the pig is shrouded in mystery. A Chinese scholar estimated his people domesticated swine about 2900 B.C. The pig was used as a scavenger before it was discovered that the flesh was good to eat. Fossil remains of the pig have been found in Europe and India, although not on the American continents. The historic swine that gave rise to the present-day pig may be basically considered as descendants of the European wild boar (*Sus scrofa*), and the Indian wild boar (*Sus cristatus*) probably developed on the Asiatic continent. The Chinese hog was brought to Europe and crossed with European hogs, thereby forming the foundation for present-day breeds. The pig belongs to the class Mammalia, or animals possessing teats for suckling their young. The pig reproduces by multiple birth, farrowing an average of 4 to 6 pigs in the wild state, and 8 to 10 pigs in the domesticated state. Pigs are rotund-bodied, short-legged, artiodactyl (having an even number of toes) animals of omnivorous habits, having thick skin from which grow short, coarse bristles, a long mobile snout, small tail and feet with two functional and two nonfunctional digits. A mature pig has 44 teeth, carries its head low, and eats, drinks and breathes close to the ground.

Swine Population and World Trade.—During the five-year period (1946–50) following World War II, the average annual world swine population was estimated at 244,900,000. In each of the following years there was a steady increase, until the world swine population reached an all-time high of 373,300,000 head in

TABLE I.—Estimated World Hog Population

Continent or Country	1946–50 (average)	1956
North America	74,500,000	74,400,000
Europe	59,300,000	95,800,000
U.S.S.R. (Europe and Asia)	13,000,000	?
Asia	58,300,000	102,800,000
South America	33,300,000	43,200,000
Africa	3,900,000	3,900,000
Oceania	2,000,000	2,100,000
Estimated world total	244,900,000	373,300,000

Source: U.S. Department of Agriculture, Foreign Agricultural Service, *Foreign Crops and Markets* (April 2, 1956).

1956 (see Table I).

Live hogs, except for breeding purposes, are not shipped long distances in world trade because of the excessive shipping space required and the costs involved. Consequently, most hog products entering world trade are shipped either in the dressed carcass, or cured or processed, at much cheaper costs. China normally exports the most live hogs, followed by such countries as Poland, Yugoslavia and Hungary. The greatest total trade in live hogs imported for slaughter is carried on by western Germany, Austria, El Salvador and Italy.

Breeds.—Domestic pigs differ from their wild ancestors and even among themselves with regard to general conformation, colour, size, disposition and other characteristics. Breeds of pigs have been developed to meet certain geographical conditions and to satisfy particular economic wants. A brief description is given of the more prominent breeds of swine throughout the world.

The *Berkshire* is a black pig with white on the face, legs and tip of tail. It originated in England, and is a prominent breed in the United States. The head is short, face dished, ears erect but inclined slightly forward. The body is compact and wide, with well-developed loin and hams. The meat is of excellent quality. The breed is early maturing but not so prolific as most breeds. The boars are used widely in crossing with other breeds for the production of market hogs.

The *Chester White* is white with a pink skin. It originated in the United States, in Chester county, Pennsylvania, hence its name. The Chester White is very prolific, has a quiet disposition, matures early, is a good grazer, a good feeder and possesses good carcass qualities. The breed is found only in the United States.

The *Duroc* breed, formerly known as the *Duroc-Jersey*, originated in the United States and ranks as one of the leading breeds in numbers. Durocs have good depth of body, good backs, as well as good feet and legs. The breed is red in colour and is noted for prolificacy, hardness and grazing ability. The mothers produce a good supply of milk. The animals are docile, grow rapidly, and mature boars and sows attain heavy weights.

The *Hampshire* breed originated in England and was later introduced into the United States. The breed is black with a white belt around its body, including the shoulders and front legs. Hampshires possess good growing and fattening qualities. The head is small, with trim jaw, erect ears and smooth, well-set shoulders. They produce a good-quality carcass. The sows are excellent mothers and suckle their pigs well. The breed crosses well with other breeds. The breed is noted for its grazing ability.

The *Hereford* breed originated in the United States. It is red in colour, with white on the head, ears, underline of body and switch of tail. It is sometimes referred to as the "White-Faced" hog, with colour markings resembling those of the Hereford breed of cattle. The Hereford hog is smaller than other common breeds. The body is compact in form, with well-sprung ribs, a medium-arched back and rather short legs. The sows are prolific. The pigs mature at an early age.

The *Landrace* pig, widely distributed in Denmark, Norway, Sweden, Germany and the Netherlands, is white in colour, and so named because the race of pigs was developed on the native land. The Danish Landrace, descriptive of those in the above-mentioned countries, is noted for its length, depth and smoothness of body, with well-developed loins and hams. The head and jaw are trim and refined, the ears large and extending over the eyes. The breed is noted for prolificacy, mothering ability and economy of feed utilization. It produces a carcass of excellent quality with a high percentage of ham, loin and bacon cuts.

The *Large Black* breed is solid black in colour and was developed in England. Large Blacks are exceedingly docile, the ears are large and hang well forward over the eyes. The breed is prolific and the sows are noted for their mothering ability. They produce a rather coarse carcass. Because of their hardness and early maturity they have proved valuable for crossing with other breeds for market. The carcass qualities of the crossbred pigs are superior to those of pure Large Black breeding.

The *Mangalitza* breed is described because of its prominence in the Balkan states of Hungary, Rumania and Yugoslavia. The

breed is either white or has a brownish-black over the body with white on the belly. It differs from other breeds in that it is primarily a fat-producer. It is late-maturing, reaching slaughter weight at two years of age or later. The fat forms in lumps and is not distributed through the lean. The lean meat is prepared in sausages or cured. The breed lacks prolificacy, litters of six being average.

The *Poland China* pig originated in Butler and Warren counties, Ohio. The breed is popular and rivals the Duroc breed in numbers. The body is black with white feet, face and tip of tail. The ears are drooping. Hogs of this breed are intermediate in type, have good length, are smooth with good width and well-rounded hams. They produce excellent carcasses. The sows are docile, good sucklers and raise pigs that gain rapidly. Mature boars may obtain weights of 1,000 lb. and over.

The *Spotted Poland China*, developed in America, resembles the black Poland China except for numerous white spots over the body. Some Gloucester Old Spots, imported from England into the United States, have influenced the development of the breed. The type of body is similar to that of the Poland China, but the ears are somewhat larger. The sows are prolific and raise good-sized litters.

The *Tamworth* pig originated in England. It is one of the oldest and probably one of the purest of all breeds of hogs. It is strictly a bacon-type breed, producing a maximum of lean meat from its long, fleshy, deep-sided carcass. The breed is red in colour and has a long narrow head, rather long snout and large erect ears often inclined forward. The pigs are good grazers but do not mature so early as some other breeds. This breed is found in small numbers in England, the United States and Canada.

Wessex Saddleback is native to England. The colour is black with a white saddle and white forelegs resembling in type the Hampshire pig found in the United States. The animals are of medium size and are considered to be good grazers and producers of good-quality carcasses.

The *Yorkshire* breed, white in colour, was developed in England and is raised widely over Europe, Canada and the United States. The animals are of the bacon type and are large, long and deep-sided, producing carcasses of excellent quality. The sows produce and raise large litters of pigs. Boars of this breed are widely used in crossing with other breeds for the production of market hogs.

New Breeds in the United States.—During the decade 1946-56, eight breeds of swine were developed at state and federal experiment stations from crossbred foundations of two or more breeds. All were accepted for purebred registration. While differing in colour, all but one were derived from crosses with the Danish Landrace as one of the parent breeds. Thus, they have much in common with respect to type, conformation, prolificacy, growth rate, feed efficiency and carcass quality. The breeds are distinguished as being intermediate in type and long bodied, and having moderate depth of body, smooth sides, straight underline, heavily muscled hams and medium length legs. The heads are long and narrow, with light jowls. The ears vary from slightly erect to drooping. Carcass quality is excellent with a high percentage of lean meat and enough fat to produce desirable quality.

TABLE II.—*New Breeds of Swine Developed in the United States, 1946-56*

Breed name*	Foundation breeds and % blood of each	Colour
American Landrace	Danish, Norwegian, Swedish Landrace 100%	White
Beltsville No. 1	Danish Landrace 75 Poland China 25	Black with white spots

Pedigree Swine Breeding.—A pedigree is a record of an animal's ancestry, similar to that of a family tree. This record may extend back to the beginning of breed history, although for practical purposes it includes only three or four generations back of the individual.

While the pig has been known for centuries, the founding of pure breeds of swine did not take place until the 18th and 19th centuries. Early breeders kept a private record of their breeding operations. As the number of animals increased, types became fixed, well-defined characters established and exchange of animals between breeds increased, it became necessary to protect the purity of breeding stock as well as interests of purchasers of purebred hogs.

Herd books were compiled to record entries for various breeds of purebred swine. The objects were to stimulate the breeding of better pigs; to increase efficiency and economy of production; to maintain uniformity of various characteristics within a breed; and to protect and promote the interest and active co-operation of breeders in the welfare of the swine industry.

The registration of purebred swine varies in different countries. Separate herd books are published by separate breeder associations in some countries, by national pig-breeder associations recording the breeds within a country or under the direction or control of a government agency created for that purpose.

Certain well-defined rules are generally applicable to data for the pedigree. The sire and dam of the animal to be recorded must be purebred and registered. Date of birth, number of pigs farrowed and weaned in the litter, name of the owner of the ancestors at time of mating and identification of pigs are required before a pedigree certificate can be furnished the owner of an animal.

From a breed improvement standpoint, a pedigree is good or bad according to the individual it represents. Regardless of pedigree an animal should not be retained as a breeder unless it meets certain standards, not only of type and conformation as judged by the eye, but also of the individual's inheritance or ability to transmit desirable characters to its offspring. Thus prolific sows that farrow and raise large litters of pigs, that make rapid and economical gains in the feed lot and that produce carcasses of suitable market quality are a credit to any breed, or breeding program.

The swine industry of Denmark has led the world in record-of-performance testing for improvement of swine. Since 1926, when record-of-performance testing of swine was begun in the United States, the value of such a program has been demonstrated. By 1944 the majority of swine associations of the United States were conducting some form of record-of-performance tests for the improvement of their respective breeds. Outstanding animals that meet high standards of production merit are given special notation on the swine pedigree. That the program is a success is attested to by the fact that the demand by breeders for animals of tested strains greatly exceeds the supply.

Nutritive Requirements.—The pig is an economical converter of feed into body tissue, the products of which furnish meat and fat for human consumption. Unlike other classes of livestock the pig has a small stomach and requires its food in concentrated form. Pigs grow more rapidly than any other class of farm animals in relation to their weight. Under good feeding and management, an average of 350 to 375 lb. of feed is required to produce 100 lb. of gain in growing and fattening pigs.

The daily ration of the pig should be properly balanced with respect to proportions of carbohydrates, proteins, minerals and vitamins. Energy which is needed for body maintenance and for gain is furnished primarily by carbohydrates and fat in the ration. Energy is also derived in part from protein metabolism. The

excess energy above maintenance requirements is stored as fat in the body. Energy requirements for maintenance vary with atmospheric temperature, increasing as temperature decreases below a critical point. The principal sources of carbohydrates are the grains commonly grown on the farm, namely, corn (maize), wheat, barley, oats, sorghums and rye.

Proteins are essential for growth of muscle, bones and the vital organs, and for body repair. As the pig grows the demand for protein decreases, while relatively larger amounts of carbohydrates are used for fat production. The proportion of protein to carbohydrates may vary from 1 to 4 for 50-lb. pigs to 1 to 7 for pigs weighing 300 lb. Although the grains contain proteins, the latter are not present in sufficient quantity or quality with respect to amino acid make-up, to promote rapid growth. High-protein feeds that possess the essential amino acids necessary to supplement the grain part of the ration are milk, tankage, fish meal, soybean meal, linseed meal, alfalfa meal and similar feeds. Combinations of two or more of the protein-rich feeds improve the quality of the ration.

Mineral and vitamin requirements can be met under ordinary conditions by the proper selection of feeds without recourse to special supplements. Calcium and phosphorus are the two most important mineral elements needed for bone development. Other elements required in small amounts are iodine, zinc, magnesium, cobalt, manganese, potassium, sodium, chlorine, copper and iron. Pasture and hay crops furnish proteins, minerals and vitamins that help correct the deficiencies of these elements in the grain ration. The vitamins known to be needed for the health and growth of the pig are vitamins A, D and the B group: thiamine, riboflavin, niacin, pantothenic acid and pyridoxine. Research has indicated that supplementing swine diets with vitamin B₁₂ and certain antibiotics usually increases growth rate and feed efficiency of pigs.

Water is essential to efficient use of feed. The amount of water consumed at will may increase from about 3.3 lb. daily for a 25-lb. pig to 12 lb. daily for a 200-lb. pig.

The requirements for the constituents of the ration will vary with the different functions performed, such as growth, fattening, reproduction and lactation. For example, young pigs to 100 lb. weight require a high level of protein in the ration; pigs from 100 to 150 lb. and sows during gestation and lactation require a medium level of protein; whereas pigs weighing from 150 to 225 lb. make efficient gains on a lower level of protein intake.

Care and Management.—Sanitation is essential to good health, rapid growth and development, and profitable pig production. Contrary to general opinion, the pig is a clean animal if given sanitary surroundings. Many pigs are forced to live in an unsanitary environment.

The raising of pigs does not require expensive equipment. The principal needs are (1) good practical houses that provide protection from the elements, freedom from draughts and proper ventilation, (2) dry bedding and (3) prevention of dust to avoid respiratory troubles. Where natural shade is not available, artificial shade is useful to prevent overheating from the sun.

In the selection of purebred animals for the foundation breeding herd, attention needs to be given to strains that are prolific, gain rapidly and utilize feed efficiently. Other considerations are uniformity of type and similarity of colour, markings and conformation. Sows are desired which show quality, length of body, femininity, and a well-developed udder, having two rows of teats with at least six teats in each row, and capable of suckling large litters of pigs. The boar should possess quality, masculinity, good disposition and ability to sire strong, vigorous pigs. A young, well-developed boar may be bred at eight months of age and mated to 20 to 30 sows during the first breeding season, whereas an aged boar may be mated to 40 to 60 sows during a season.

The period of oestrus (or heat) in the sow is about three days, and mating with the boar should take place the second or third day. If not pregnant, the sow comes in heat every three weeks. The gestation period is 112 days. Much of the success of pig raising depends on the care and management during this period. Suitable feed and ample exercise are important during pregnancy. When practicable, sows and gilts are sorted and fed in separate

groups. Gilts may be bred at 8 to 8½ months of age to farrow their first litter when one year old. After that two litters a year may be produced and the sow retained as long as her usefulness continues. The amount of feed is regulated to have the animal in good condition at farrowing time, but not too fat. Accurate breeding dates should be maintained and sows and gilts removed to a cleanly prepared individual farrowing pen three days before they are due to farrow. Providing pens with guard rails helps prevent sows from crushing their young. The use of an electric pig brooder furnishes warmth and prevents chilling of young pigs. The ration of the sow needs to be reduced several days before farrowing, then gradually increased after farrowing so as not to disturb the digestive system of the newborn pigs. Special attention should be given to prevent loss of pigs during the first two weeks of life, when most losses occur.

Newborn pigs depend on the milk of their mothers for the first three weeks. After that they eat supplementary feeds in addition. Pigs are weaned from their mothers at 6 to 10 weeks of age. They should then be well fed and cared for during the growing and fattening period to produce rapid and economical gains. One or a combination of several methods of feeding may be followed, namely, hand feeding, limited feeding, self-feeding or hogging-down crops. Rotation of pastures and placing of pigs on land not occupied by pigs during the previous year will lessen danger of parasite infestation.

Diseases of Swine.—The most devastating disease of swine, the world over, is hog cholera (swine fever) (see SWINE FEVER). This contagious malady affects swine of all ages and breeds and is caused by a virus. Other species are not susceptible.

The virus is present in the blood and excretions even before symptoms appear and may be spread to susceptible swine from these sources either directly or indirectly by man, birds or flies. Feeding uncooked swill, or garbage, that contains infected pork, and purchasing unvaccinated pigs from public markets are especially hazardous.

Methods of prevention are the simultaneous hypodermic injection of graduated quantities of hog cholera virus and anti-hog-cholera serum or the use of live attenuated virus with or without serum. Drugs are ineffective for either prevention or treatment.

Hog cholera should not be confused with African swine fever, another virus disease, although the two appear similar.

Erysipelas is a bacterial disease prevalent in Europe and the United States. The acute form appears much like swine fever; the chronic form is characterized by heart valve lesions, arthritis, unthriftiness, and necrosis of the skin, tail and ears. Some other species, including man, are susceptible, but are less frequently affected. However, in turkeys the disease may cause high mortality. For immunization, live cultures of the causative organism, *Erysipelothrix rhusiopathiae*, are used with specific hyperimmune serum, or killed cultures may be used without serum. The serum has considerable therapeutic value and penicillin is highly effective in treating the acute disease.

Enteritis causes considerable losses in swine. The most widespread and serious form is attributed to *Salmonella choleraesuis*, which commonly occurs with swine fever. Haemorrhagic dysentery, caused by *Vibrio coli*, is another form of infectious enteritis. Transmissible gastroenteritis in baby pigs, caused by a virus, spreads very rapidly and mortality is high. Additional deaths in unweaned pigs may arise from poor sanitation, improper nutrition, chilling, parasitism and genetic weaknesses.

Tuberculosis is contracted by swine from chickens, cattle and man. The chief loss from the disease results from condemnation of heads because of localized lesions in the cervical lymph nodes found during meat inspection. Successful control or eradication depends chiefly upon preventing exposure.

Brucellosis, caused by *Brucella suis*, is characterized by abortions and localized infections, chiefly in the vertebrae, joints and testes. The disease spreads almost exclusively from pig to pig.

It may be detected by periodic blood tests. Treatment is ineffective. Man develops a severe form of undulant fever from *Brucella suis*.

Influenza, swine pox, ictero-anaemia and atrophic rhinitis in swine over ten weeks of age, and nutritional anaemia in suckling pigs also cause death losses and impaired health in swine.

Leptospirosis is caused chiefly by *Leptospira pomona*, although other species are incriminated in certain areas of the world. Pregnant sows may abort or farrow small, weak or dead pigs. Swine other than pregnant sows usually have a mild or inapparent infection and mortality is low. The chief source of infection is carrier animals which pass leptospirae in the urine for several months. The disease can be diagnosed by blood tests or finding the organism in the urine. A bacterin made from killed organisms successfully immunizes swine, and antibiotics are effective in treatment. The disease is transmissible to man.

Good swine husbandry emphasizes good breeding, proper nutrition and strict sanitation, all of which help to control diseases.

BIBLIOGRAPHY.—F. Hutyra *et al.*, *Special Pathology and Therapeutics of the Diseases of Domestic Animals*, 5th Eng. ed., 3 vol. (London, 1947); W. A. Hagan and D. W. Bruner, *Infectious Diseases of Domestic Animals* (Ithaca, London, 1951). (M. S. Sn.; V. L. S.)

Parasites of Swine.—The most serious parasites of swine are roundworms, although protozoa and mites may sometimes be of considerable importance. The U.S. department of agriculture estimated in 1954 that parasites of swine cause an annual loss of \$279,826,000 in the United States alone.

Ascaris lumbricoides is the most injurious roundworm of swine. The adult worms are found in the small intestine, where they compete with their host for food. Even more serious are the effects caused by the migration of the larvae. The females lay eggs, which pass out of the body. Infective larvae develop inside the eggs on the ground. These embryonated eggs are very resistant to the effects of heat, cold, sunlight and chemicals, and may remain alive in the soil for more than four years. When they are swallowed by a pig they hatch in the intestine, and the larvae migrate to the liver and lungs, where they undergo some growth. They are then coughed up and swallowed, and finally become adults in the small intestine. The migrations of the larvae damage the liver and lungs, causing pneumonia, difficult breathing, stunting and even death.

Control consists in following a system of sanitation known as the McLean County system, first extensively tested in 1920 in McLean county, Ill. Briefly, the system consists in washing the sows before farrowing and placing them in thoroughly cleaned and disinfected farrowing quarters. After farrowing, the sows and pigs are kept in the houses until the pigs are from two to four weeks old, and are then hauled—not driven—to a clean pasture, where adequate shelter and feed are provided. Even better sanitation can be obtained if the pigs are raised on concrete throughout their lives. With due attention to the details of the system, a high percentage of the pigs which are farrowed can be raised, and the pigs can be marketed four to eight weeks earlier than if kept under average conditions. In addition, the system saves feed and controls many other parasites and infectious diseases.

Piperazine, sodium fluoride or cadmium oxide can be used to remove the adult worms. In treating pigs, these compounds are ordinarily mixed with the feed.

Lungworms are also injurious. They live in the bronchial tubes, where they cause pneumonia and unthriftiness. In addition, they may transmit the virus of swine influenza. Lungworms require earthworms as intermediate hosts before their larvae can develop to the infective stage. Pigs become infected by eating infected earthworms.

Another roundworm is *Trichinella spiralis*. The tiny adults are found in the intestine, while the larvae occur in the muscles, where they cause the painful and sometimes fatal disease, trichinosis. This disease is serious in man, but swine seldom show symptoms. Swine become infected largely through eating pork trimmings in uncooked garbage or slaughterhouse offal, or by eating dead pigs, rats or other animals which harbour the encysted larvae. Man ordinarily becomes infected by eating uncooked or improperly cooked pork. Human infection can be prevented by cooking pork

thoroughly. Infection of swine can be largely prevented by cooking all garbage fed to them.

Other injurious roundworms of swine include whipworms, which attach themselves to the wall of the caecum, and kidney worms, which injure the liver, kidneys and other organs.

The large thorny-headed worm, *Macracanthorhynchus hirudinaceus*, attaches itself to the wall of the small intestine, causing a nodule to form. Its intermediate host is the white grub, which is the larval stage of the May beetle; pigs become infected by eating infected grubs or beetles.

Swine normally are not infected with adult tapeworms. They are, however, intermediate hosts of the pork tapeworm of man, *Taenia solium*. The larva of this parasite occurs in the heart and muscles of swine, and man becomes infected with the adult worm by eating inadequately cooked pork.

Flukes are relatively unimportant, but may be encountered in some parts of the world, especially the Orient. Three of these, the large intestinal fluke, *Fasciolopsis buski*, the lung fluke, *Paragonimus westermani*, and the blood fluke, *Schistosoma japonicum*, also occur in man, and swine may spread them unless proper sanitary precautions are observed.

Lice and mange mites are the principal external parasites of swine. They may cause unthriftiness and low vitality. Lice and mange mites can be eradicated effectively by dipping swine in crude petroleum or in lindane or benzene hexachloride dips. Sprays containing lindane, benzene hexachloride, chlordane or toxaphene can also be used. DDT is effective against lice, but not against mange mites.

Swine have many intestinal protozoa. Some are harmless, but others cause disease. Coccidiosis is a diarrheal disease caused by *Eimeria deblickei* and related protozoa. They invade and destroy the epithelial cells of the intestine. The ciliate, *Balantidium coli*, is found in about two-thirds of all swine and also occurs rarely in man. It is usually harmless, but may occasionally invade intestinal lesions started by other micro-organisms. (N. D. L.)

PIGEON, a name of Norman introduction for certain birds of the family Columbæ (see DOVE). Perhaps the best-known species to which the name is exclusively applied is the passenger pigeon (*Ectopistes migratorius*) of North America. Formerly nesting in countless multitudes in the then "backwoods" of Kentucky, Ohio and Indiana, this bird is now extinct, the last specimen dying in the Cincinnati Zoological gardens in 1914. The passenger pigeon was about the size of a turtledove, but with a long, wedge-shaped tail. The male was a dark slate colour above and purplish bay below; the female, drab above, dull white beneath.

The beautiful fruit pigeons (*Treron*) of tropical Africa, India and the Malay archipelago are among the most delicately coloured of all birds.

The largest forms are the giant crowned pigeons (*Goura*) of New Guinea; they have a beautiful filmy, fan-shaped crest on the head.

The Nicobar pigeon (*Caloenas*) is remarkable for the long lustrous neck hackles and its peculiar gizzard.

Pigeons lay two or three white eggs and the naked, helpless young are fed by a secretion from their parents' crops ("pigeon milk").

PIGEON-FLYING. All pigeons biologically trace back to a common ancestry, the Blue Rock pigeon. In the process of domestication they have branched off into varieties, fostered and developed by man, for utility purposes or merely for the pleasure of keeping them as pets. The homing pigeon is a distinct variety created through the careful cross-breeding of several other varieties, with the thought in mind of obtaining maximum distance and speed in controlled and directed flight. The homing pigeons are grouped in families or strains usually identified by the names of pigeon fanciers of prominence who have bred selected groups for many generations, thereby developing certain characteristics of performance and appearance.

The earliest record of pigeons kept under domestication occurs in the fifth Egyptian dynasty about 3000 B.C. An actual pigeon-post system was established in Baghdad by the sultan in 1150.

The system was immediately destroyed when Baghdad fell into the hands of the Mongols in 1258.

Pigeons were used extensively as messengers during the French Revolution of 1848. The messages were then printed in the French and Belgian newspapers. In 1849 telegrams were handled over a portion of the distance between Berlin and Brussels by pigeons in order to bridge a gap in telegraph lines.

Belgium may be considered as the home of the racing pigeon sport. In 1818, the first long distance race of over 100 mi. was held, while in 1820 there was a race from Paris to Liège, and in 1823 from London to Belgium.

The sport is a favourite one in Great Britain, the United States and France. However, nowhere does it attain the general popularity which it enjoys in Belgium, where nearly every village has its *société colombophile*, or pigeon club. The annual Belgian Concours National, a race of about 500 mi. from Toulouse to Brussels, was inaugurated in 1881, and in this same year the first regular races in Great Britain, from Exeter, Plymouth and Penzance to London, took place.

Loft Construction.—The loft should be on a commanding site and may be a building or vehicle designed and equipped for that purpose. An aviary is a part of a loft, usually built of wire netting open on the sides and roof, in which pigeons are given access to more sunlight than when in the loft proper. Perches are placed on the inner sides of the loft walls and a trap is specially constructed to permit the pigeon free passage into but not out of the loft. In front of the trap is placed a landing board upon which pigeons alight when about to enter the loft. A trap that permits the pigeon to enter and leave the loft at will is known as an "open trap." The loft is provided with drinking fountains, bath pans, grit boxes and other equipment necessary for maintaining sanitary measures.

Training.—All homing pigeons except those specifically reserved for breeding purposes may undergo training continuously from the time they are 28 days of age. This training consists of teaching them to enter the loft through the trap, exercising around the loft, and returning to the loft when given liberation at points distant from the loft. The pigeon's desire to return to its loft is largely based on the natural urges of hunger and reproduction and, being monogamous, the latter may often be greater than the former. The strain, physical condition, training and treatment of the bird largely determines its speed and reliability. Fog, snow, rain and adverse winds, or any other conditions of the weather which reduce visibility or oppose the flight of the pigeon, decrease its efficiency. The basic requirement of training homing pigeons for racing is to accomplish a state of good health and the necessary strength to endure sustained flight. Good health is dependent upon the sanitation of the loft, proper feeding of a suitable diet, ventilation, and uncontaminated drinking water. A pigeon's diet should include leguminous seeds, cereal grains, green foods and grit. The seeds and grains are fed as an ordinary diet in the form of a feed mixture. All seeds and grains, regardless of type, should be clean, sound, and of a good natural colour and odour. The strength of the bird is increased by exercise flights around the loft, and by the training flights the bird may receive from points that are distant from the loft.

Pigeon fanciers generally divide their birds into two classes, one for breeding and the other for racing, though the latter are allowed to breed within certain limits. At the start of a race the birds competing are banded with a rubber countermark, they are then liberated together by a starter who takes the time of release. The birds ascend rapidly, become oriented and head directly towards their loft usually following the line of least resistance.

As the birds enter their home lofts, the rubber countermark is removed from the leg and placed in a pigeon timer which indicates the time of arrival. The distance of the pigeon's flight is divided by the time consumed to determine which pigeon has made the fastest speed. A bird is not considered to have arrived "home" until actually through the trap of its loft.

The training of pigeons for army use as a means of communication is similar to training for racing; however, messages

are attached to the pigeon's leg or back by means of capsules specially designed for that purpose. (W. H. KN.)

PIG IRON. Crude cast iron, run from the blast furnace directly into moulds. The moulds originally were of sand formed in a way which suggested a nursing litter of pigs. (See IRON AND STEEL; BLAST FURNACE.)

PIGMENTS: see PAINTS, CHEMISTRY OF.

PIGMENTS OF SKIN AND HAIR. Skin and hair colour is determined by several types of coloured materials or pigments.

The Colour of Normal Skin.—The normal colour of human skin is derived principally from the following pigments: (1) melanin, a granular, water-insoluble, brown substance; (2) carotene, the same yellow pigment found in butter and carrots; and (3) haemoglobin, the red pigment of blood. Additional factors modifying the final colour effect are the chemical and physical states of these pigments, their distribution patterns in the skin, and the optical properties of the overlying tissue layers. The deeper any dark pigment is situated in the skin the more bluish it appears from the surface because, whereas other colours are absorbed by the dark pigment, the blue component of light impinging on the skin is appreciably scattered before reaching the pigment by the turbid, though essentially colourless, overlying tissue layers. It is this same blue-light scattering effect by small dust particles in the atmosphere that makes the sky appear blue.

Changes in the amount and degree of oxygenation of blood in the upper portions of the skin greatly influence its colour. If the amount of oxygenated blood near the surface is increased by dilatation of superficial tiny blood vessels called capillaries, as occurs in blushing or acute inflammatory processes, the skin becomes pink because the bright red colour of oxyhaemoglobin blood pigment can be readily perceived. When the amount of blood near the surface is decreased, as when a person is about to faint, the skin becomes pale. If the blood near the skin surface is not sufficiently oxygenated, the bluish colour of reduced haemoglobin becomes evident and the skin is said to appear cyanotic. Cyanotic skin is characteristically seen in suffocating individuals, in so-called blue-babies, and wherever the blood circulation to the skin stagnates.

The yellow pigment carotene is present in the fatty tissues below the skin and also in the closely packed horny scales that comprise the outermost dead layers of the skin. Thus the skin has a more pronounced yellowish hue wherever the fatty tissues just below the skin are abundant or where the horny layer is particularly thick as over the palms and soles.

Melanin Pigmentation.—Melanin is the most characteristic pigment of the skin. It is present in all races. Racial differences in skin colour are based almost exclusively on differences in melanin content. Only in a few individuals is melanin pigment completely absent. This abnormal condition is called total albinism and is an inherited anomaly (Mendelian recessive).

Melanin is found distributed throughout practically the entire living world and yet its only apparent function is a pigmentary one. This function has been elaborated by many lower forms into complex and important mechanisms for camouflage and sexual attraction. The elaborateness of some of these mechanisms can be illustrated by the "ink" of squids, by the various striped and spotted and seasonally changing coat patterns of animals, and even more so by the remarkable adaptive colour changes possible in certain fishes, amphibians and lizards. In the flounder especially the high degree of control over melanin distribution pattern by precise nervous and hormonal mechanisms permits it to mimic accurately both the colour shade and pattern of its background. (See MIMICRY.) As a pigment, melanin also serves to offer some protection against the harmful effects of excessive sunlight radiation and is an essential component for efficient function of the eye. In man, variations in melanin pigmentation have in addition acquired well-known cosmetic and social significance.

Melanin pigment is produced in the skin in a network of specialized cells scattered through the basal layer of the epidermis (the thin, richly cellular, outer part of the skin). These cells, having many long, slender, pseudopodlike processes, are called melanocytes and they derive developmentally from a type of em-

bryonic nervous tissue precursor called the neural crest. Some freckles represent genetically induced spotty accumulations of melanocytes. Pigmented moles are harmless overgrowths of these same cells. Quite different are the dreaded melanotic malignant tumours or black-cancers which, though arising from melanocytes, rampage into uncontrolled fatal invasive growth. The danger of common moles degenerating into such malignant tumours has been greatly exaggerated in popular medical writings.

Melanin granules in melanocytes develop around some of the very minute particles in their cell substance called mitochondria. These particles possess an oxidative enzyme, tyrosinase, which brings about the chemical conversion by oxidation of tyrosine, a component of protein, to melanin. Copper is an essential constituent of tyrosinase. The chemical process by which melanin is formed was first studied in plants and in lower forms of the animal kingdom. For experimental purposes tyrosinase was extracted from potatoes or meal worms. If solutions of tyrosine and such tyrosinase are mixed and left exposed to air, the colourless mixture first becomes red and then gradually turns to a dark brown. The melanin thus formed precipitates in granular form. In the 1920s, in a brilliant series of experiments, H. S. Raper succeeded in isolating the intermediate compounds of this reaction. However, the very last step of the chemical process by which the red substance turns brown and precipitates remained obscure; the exact chemical structure of melanin was still unknown in the 1950s. If dopa (an abbreviation for dihydroxyphenylalanine), the first oxidation product of Raper's series in the tyrosine-tyrosinase reaction, is added to tyrosinase it too is rapidly oxidized to melanin. In 1917, even before tyrosinase was found in skin, Bruno Bloch demonstrated that if fresh sections of human skin are immersed in a solution of dopa, new melanin granules appear in them. This dopa reaction is a useful indicator of the faculty of melanin formation in any kind of tissue.

The colour of melanin varies from light tan to dark brown, depending on its degree of oxidation. In winter the average normal white person's skin is rather pale. Nevertheless, such skin still contains a great amount of melanin of the pale variety which can be oxidized to a darker melanin by exposure to sunshine or heat. However, darkening by sunshine of preformed melanin must be sharply distinguished from true tanning such as that which develops slowly after sunburn and which implies accelerated formation of new melanin granules. The former can be achieved by long-wave ultra-violet rays which penetrate ordinary window glass, whereas the latter is brought about by ultra-violet rays of shorter wave lengths which are absorbed by such glass. The fashionable sun tan oils screen out sunburn wave lengths and yet do not hinder the long-wave pigment darkening rays.

Melanin Pigment Regulatory Mechanism.—Tyrosinase in skin is normally believed present in a partially inhibited state. Copper binding substances (sulfhydryl compounds) in the epidermis probably account for the inhibition by preventing full utilization of this element by the enzyme. Various pigment-stimulating factors such as ultra-violet rays and inflammation can release this inhibition by causing a decrease in the copper-binding substances in the epidermis.

In lower vertebrates, pigment granule dispersion or aggregation within melanocytes is under nervous and hormonal regulation which permits sudden spectacular changes in skin colour. Melanophore hormone secreted by the pituitary gland at the base of the brain causes dispersion of pigment granules in melanocytes, thus darkening the animal's skin. The darkening of frogs in a cold environment is produced by this hormonal mechanism.

Although melanophore hormone is produced in mammals and man, its role in influencing skin colour in these organisms had not been completely established at mid-20th century. In man, endocrine gland influences on pigmentation are illustrated by the excessive melanin formation in Addison's disease (*q.v.*), a serious condition caused by adrenal gland destruction; and by the direct stimulating action of female sex hormone (estrogen) on melanocytes in certain areas such as the nipples, midline of the abdomen and genitalia. Increased amount of circulating estrogen accounts for the darkening of these areas during pregnancy. The hyper-

pigmentation of Addison's disease has been related to increased melanophore hormone production by the pituitary gland as a consequence of lack of adrenal gland hormone inhibition of the pituitary.

Abnormal Pigments.—The skin colour may be modified by the deposition of abnormal pigments. Among these are: haemosiderin, an iron-containing pigment deriving from haemoglobin and causing a brown or bronzelike discoloration which can be distinguished from melanin pigmentation only by special microscopic examination; bilirubin, a bile pigment causing the yellow colour of jaundiced persons; and silver, which leads to a grayish-blue skin colour (argyrosis) when silver salts are taken internally in excessive amounts. Excessive internal administration of salts of gold and bismuth can lead to deposition of these metals as abnormal pigments in the skin in a fashion analogous to silver.

The Colour of Hair.—The mechanism of pigment formation in hair and feathers is essentially the same as in the skin. Melanocytes are present in the basal layer of the root of the hair. According to their genetic potentialities, these melanocytes form, more or less, coarse or fine melanin granules which ascend together with the growing hair. It is generally agreed that blond, red, brown and black human hair contain melanin. The colour differences depend on differences in amount, size and distribution of the granules, and their degree of oxidation. Bright red hair of humans, however, is a remarkable exception in so far as it contains, in addition to melanin, an iron pigment. Its role in the formation of the red colour was not yet understood at mid-century.

The continuous production of pigment in the germinative layer of growing hair requires adequate nutrition. In unusual states of malnutrition, particularly in the absence of vitamin B factors and copper in the food, graying of the hair may occur. The original colour returns when the lacking food factors are added to the diet. The natural graying of hair in the aging person, however, has nothing to do with nutritional deficiencies and cannot be cured by administration of vitamins. It represents an irreversible exhaustion of the melanin-forming enzyme which occurs early or late according to genetic determination. The myth of sudden graying of hair following psychic shock is a biologically absurd assumption. (See also HAIR; RACES OF MANKIND; SKIN AND EXOSKELETON.)

PIGOT, GEORGE, BARON (1719-1777), English governor of Madras, was born on March 4, 1719 and entered the service of the East India company in 1736. He became governor and commander in chief of Madras in 1755. Having defended this place against the French in 1758-59 and occupied Pondicherry on behalf of the company, he resigned office in Nov. 1763 and returned to England, being made a baronet in 1764. In the following year he obtained a seat in parliament, which he retained until his death; in 1766 he was created an Irish peer as Baron Pigot. Returning to India in 1775 to occupy his former position at Madras, Pigot was at once involved in a quarrel with the majority of his council, which arose out of the proposed restoration of the rajah of Tanjore. The governor was arrested by order of his opponents and was still a prisoner when he died on May 11, 1777. In 1779 the matter was discussed in parliament, and four of those who were responsible for his arrest were tried and fined £1,000 each. Pigot, who left several illegitimate children, was never married, and his barony became extinct.

PIG-STICKING or **HOG-HUNTING** is the sport of chasing the wild boar on horseback with a spear. From the earliest times the pursuit of the wild boar was a favourite pastime in Europe but the modern sport of pig-sticking is of Indian origin. It is now

generally accepted as a fact that pig-sticking was the outcome of bear-spearing, which was popular among British sportsmen in Bengal until the beginning of the 19th century when bears had become so scarce that wild boars were substituted as the quarry. Early in the 19th century it seems that the spear was generally thrown, and Captain Johnson, writing in 1827, gives directions for throwing the spear, which was a weapon more in the nature of a javelin with different coloured ribbons attached to the butt so as to enable the owner to reclaim his spear. In 1830 the jobbing, or thrusting, spear was introduced, and this weapon was universally used in Bengal. But the jobbing spear was known before 1830 and was used regularly by officers of Lord Lake's army as early as 1803 (see *War and Sport in India: an Officer's Diary, 1802-1806*). There are really three types of spear subsequently adopted for general use: the short Bengal spear which is about 5 ft. long and is always used overhand; the long Bombay spear, which may be as long as 10 or 12 ft. and is always used underhand like a lance; and a spear about 6 to 7 ft. long, which is well led at the butt so as to balance about a foot from that end and generally used underhand but which can, should circumstances so demand, be used overhand. The best type of horse is one that is fast and quick, yet not too big, as very rapid twists and turns must be made when following a pig which "jinks," or turns sharp in its tracks. For this same reason the horse must be perfectly balanced and well back on its hocks, while a good shoulder and long rein help it to stand up over bad ground.

A large area of land was controlled and hunted by a Tent club corresponding to a hunt in England, and private expeditions after pig in any such area were forbidden by etiquette. The season varied in different districts but began as soon as the heavy undergrowth, which springs up during the monsoon, had died sufficiently to enable riding across country, usually in January, and continued throughout the hot weather until the rains toward the end of June. April, May and early June are the best months. Meets of a Tent club took place, as a rule, once a fortnight, lasting for two to four days. There are two methods of hunting. Where the whole country is covered with girth-high grass and jhow (tamarisk), a long line of beaters advanced while the "spears" rode with the line. These were divided into "heats" of three or four, and only one heat might ride a boar that was put up, or "reared," by the beaters, the heat nearest the boar taking the hunt. The rider gaining "first spear," that is who speared the boar first, claimed the head and tusks as his trophy. But where the boar inhabited thick patches of unridable jungle, the heats waited in hiding outside, while beaters drove out the boar. The rules for riding were the same in both cases.

There were various pig-sticking competitions the best known of which is the Kadir cup. The word "Kadir" (pronounced "Karder") merely means the old bed of a large river. All the big Indian rivers are constantly changing their courses and the land which has at one time been under water may be anything from 5 to 30 mi. in width. Such land is a river Kadir and is overgrown with tamarisk and grass, intersected with nullahs (i.e., water courses, dry or full of water) and dotted with *jhils* (swamps). Villages are few and far between, while the ground is the haunt of wild boar and many other species of game, both big and small.

The winning of the Kadir cup, which was instituted in 1869, constituted the blue ribbon of pig-sticking. Other pig-sticking competitions were the Guzerat cup, run on similar lines to the Kadir cup; the Nagpur Hunt cup, which went to the member of the Tent club gaining the greatest number of first spears in the season; and the Muttra cup, which was instituted in 1913 and awarded to a team of three actually killing the greatest proportion of boars to those hunted.

Useful books on the subject are: F. B. Simpson, *Letters on Sport in Eastern Bengal*; A. E. Wardrop, *Modern Pig-Sticking*; Sir Robert S. S. Baden-Powell, *Pig-Sticking or Hog-Hunting*. (G. Bu.; X.)

PIGWEED, a name applied to various plants, especially lamb's-quarters (*q.v.*) and various species of amaranth (*q.v.*). The winged pigweed (*Cycloloma atriplicifolium*), of the Great Plains region of North America, is closely allied to lamb's-quarters.

PIKA, a small, tailless rabbit-like mammal (*Ochotona*), found in northern Asia and the mountains of North America, one species ranging into eastern Europe. The ears are smaller than those of rabbits, and rounded; the hind feet are hardly longer than those of a squirrel, and the collarbone is complete. The soles of the feet are hairy and the fur is soft and thick. Pikas inhabit cold and dry regions, usually dwelling in chinks between the rocks or in burrows. One Himalayan species is found in pine forests and other Asiatic pikas inhabit steppe country. They are very active, often busily gathering food in the daytime. Large piles of vegetation are collected and dried in the sun to make "hay," then stored under rocks for the winter. Their voice is a whistling "bleat," penetrating and ventriloquistic. Pikas are usually coloured much like the rocks among which they dwell, dark gray with a mixture of ochraceous. They are about the size of a guinea pig, reaching a length of about eight inches.

See RODENTIA; also J. L. Bouhote, "The Mouse-Hares of the Genus *Ochotona*," *Proc. Zool. Soc.* (London, 1905) and A. H. Howell, *North American Fauna*, No. 47 (1924). (J. E. Hl.)

PIKE, ZEBULON MONTGOMERY (1779-1813), American explorer and soldier, was born at Lamington, Somerset county, N.J., the son of Zebulon Pike (1751-1834) a captain in the Revolutionary War, who remained in federal service until 1812. The son entered his father's company as a cadet about 1794, and in 1799 or 1800 was commissioned first lieutenant. When in 1805 President Jefferson wished the upper Mississippi region of the Louisiana Purchase explored, Lieut. Pike, then 26 years of age, was selected to lead the expedition. With 20 soldiers he ascended the Mississippi from St. Louis past the Falls of St. Anthony to a place in Morrison county, Minn. Hence he made an expedition on foot to the fur-trading posts of the Northwest company, a British concern, at Sandy, Leech and Cass lakes, and took formal possession for the United States. He returned to St. Louis in April 1806, and almost immediately was dispatched at the head of an expedition to treat with Indian tribes and explore the country west and southwest of St. Louis to the headwaters of the Arkansas and Red rivers. After holding a grand council of the Pawnees, he ascended the Arkansas river through the Royal Gorge, and came in sight of the mountain which was named Pikes Peak in his honour. While searching for the Red river he came to the South Platte, marched through South Park, left it by Trout Creek pass, struck over to the Arkansas, which he thought was the Red river for which he was searching, and, going south and southwest, came to the Rio Grande del Norte (about where Alamosa, Conejos county, Colorado, is now) on Jan. 30, 1807. There on Feb. 26 he and a small number of his men were taken prisoners by Spanish authorities, who sent him first to Santa Fe, then to Chihuahua to General Salcedo, and by a roundabout way to the American frontier, where he was released on July 1, 1807. He was promoted captain (Aug. 1806), major (May 1808), lieutenant colonel (Dec. 1809) and colonel (July 1812). In 1808 he tried in vain to get an appropriation from congress for himself and his men. He was military agent in New Orleans in 1809-10, was deputy quartermaster general in April-July 1812, and was in active service in the War of 1812 as adjutant and inspector general in the campaign against York (now Toronto), Canada, and in the attack on York on April 27, 1813, was in immediate command of the troops in action and was killed by a piece of rock which fell on him when the British garrison in its retreat set fire to the magazine, just as his victorious soldiers were breaking in.

His *Account of an Expedition to the Sources of the Mississippi and through the Western Parts of Louisiana . . . and a Tour through the Interior Parts of New Spain* was published at Philadelphia, 1810; rearranged and reprinted in London, 1811, and has been published in many editions since, including translations into the French and Dutch. The standard edition with memoir and notes by Elliott Coues was published in 1895. In 1908 H. E. Bolton published some of the papers taken from Pike in Mexico (originals then in Mexican archives but forwarded to Washington in 1910) in the *American Historical Review* (vol. xiii, 798-827).

See the sketch by H. Whiting in vol. V, Ser. 2, of Jared Spark's *Library of American Biography*.

PIKE, fresh-water fishes generally distributed over the rivers and lakes of Europe, northern Asia, and North America, and forming a small family (Esocidae) of soft-rayed fishes. They are recognized by their elongate compressed body covered with small scales, a long head, long spatulate snout, and large mouth armed with strong and long teeth in the jaws and broad bands of smaller teeth on the palate and tongue. The teeth point backward or can be depressed so as to offer no obstruction to any object entering the gape, but prevent its withdrawal in the opposite direction. The dorsal and anal fins are placed far back on the tail, thus greatly increasing the propelling power of the fish. Although pike lead rather a sedentary life, they are excelled by no other fresh-water fish in rapidity of motion when they dash upon their prey or dart out of reach of danger. In the old world one species only is known (*Esox lucius*), which prefers lakes and sluggish reaches of rivers. It extends into Lapland in the north and as far south as central Italy and Constantinople, but is absent in Spain and Portugal. The European species occurs also in eastern North America, and is common southward to northern Ohio.

PIKE (*ESOX LUCIUS*)

But North American waters are tenanted by other species of pike of which the largest is the muskellunge or maskinonge of the Great Lakes (*E. masquinongy*). The other American pike are smaller and generally named "pickerel." Pike are the most voracious of fresh-water fish. Large specimens will seize rats or water-voles, and are said to attack even foxes and small dogs. Individuals of *E. lucius* of 50 lb. are not scarce, but much larger ones are on record. Pike as food are much esteemed inland. According to season and climate they spawn in April or May and sometimes as early as February.

PIKE, a word which, apart from the use as the name of the fish (see above), is probably a shortened form of pike-fish, from its sharp, pointed beak. Common uses of the word are for a long hafted weapon with sharply pointed head of iron or steel, the common weapon of the foot-soldier till the introduction of the bayonet (see articles HALBERT and BAYONET), and for a hill with a pointed summit, appearing chiefly in the names of such hills in Cumberland, Westmorland and northwest Lancashire.

PIKE-PERCH, fresh-water fishes allied to the perch, but with strong teeth standing between smaller ones. They resemble the pike in their elongate body and head, and are dangerous enemies to other fresh-water fishes. They are excellent eating. In Europe two species occur, the more celebrated being *Lucioperca sandra*. It prefers the quiet waters of large rivers and clear, deep lakes, in which it reaches a weight of 25 to 30 pounds. The second (*L. wolgensis*) is limited to rivers in southern Russia and Hungary. In North America two or more are distinguished; viz., *L. vitrea*, which grows to a weight of 20 lb., and the smaller *L. canadensis*; both are abundant in the Canadian lakes and upper Mississippi, and the latter also in the Ohio.

PIKES PEAK, a famous mountain of the Rampart range of the Rocky Mountains in El Paso county, Colorado, U.S.A. Though surpassed in altitude (14,110 ft.) by many summits in the state, few have so commanding a location and none is so well known. From the summit the magnificent Sangre de Cristo range is in the foreground, while on a clear day not only its southernmost summit, Blanca Peak (14,310 ft.) is visible, but also the Spanish Peaks (12,708 and 13,623 ft.) 100 mi. to the south, and Longs Peak 100 mi. to the north, and between them Mt. Lincoln, Grays Peak and other giants, while the view extends eastward over a vast sweep of plains. At the base of the mountain are Manitou Springs and Colorado Springs, whence tourists can make the ascent of the peak on horseback, by a cog-railway, 8.75 mi. long (opened in 1891), or by a well constructed automobile road.

The lower slopes are covered with evergreen forests but the upper 2,500 ft. of the peak is bare granite. The summit covers an area of from 10 to 15 ac. Pikes Peak was discovered in Nov. 1806 by Lieut. Zebulon M. Pike. In 1819 it was first climbed by the exploring party of Major S. H. Long.

PIKES PEAK OCEAN TO OCEAN HIGHWAY, an American highway extending from New York city to San Francisco, Calif., a distance of 3,564 mi. Its central location makes it one of the most direct routes from ocean to ocean. From New York city to Pittsburgh, Pa., this highway is also known as the William Penn highway. Columbus, O., Indianapolis, Ind., Springfield, Ill., St. Joseph, Mo., Colorado Springs, Colo., Salt Lake City, Utah, Reno, Nev., and Sacramento, Cal., mark the general course of the highway.

PILATE, PONTIUS, of equestrian rank, was Roman governor of Judaea from A.D. 26 to A.D. 36, when he was recalled. He kept the Roman peace in Palestine, but with little understanding of the people (Josephus, *Ant.* XVIII, iii, 1, 2; iv, 1, 2; *Jewish War*, II, ix, 2-4, Philo, *ad Caium*, 38). One disturbance arose when Pilate used Temple funds for an aqueduct. The reference in Luke xiii, 1, to the massacre of Galilean pilgrims in the act of sacrificing suggests the governor's ruthlessness in putting down riot. It must be said, however, that the post of Roman governor in Judaea was peculiarly difficult, and it was to Pilate's credit that his rule lasted as long as ten years. Both Pilate's part in responsibility for the crucifixion of Jesus Christ and the legal aspects of the trial have been much debated. The early church blamed the Jews, and correspondingly tended to exonerate Pilate. The Third and Fourth Gospels, especially, suggest that extraordinary pressure was brought to bear upon the governor by the Jewish priests. Pilate may well have been impressed by the dignity and gentleness of the great Preacher of the Kingdom of God, and may also have given Him opportunity to save Himself (John xviii, 33-38; xix, 9-11). There are many stories, all of uncertain value and in many cases legendary, telling of Pilate's later life and of his suicide. Pilate has been canonized in the Abyssinian church (June 25) and his wife Procla, or Procula, in the Greek (Oct. 27).

PILCHARD or **SARDINE**, fish of the herring family (Clupeidae) with the fore margin of the dorsal fin situated in advance of the mid-point between the tip of the snout and the base of the caudal fin, with the lower jaw not prominent and with the operculum having grooves radiating toward the suboperculum. One species is known in Europe, *Sardina pilchardus*, which is characterized by a remarkably peculiar arrangement of scales, in which alternate oblique rows of small scales are covered by intervening rows of larger ones. This species occurs from Portugal north to the English channel. A subspecies, *S. p. sardina*, occurs from the Canary Islands to the Mediterranean and into the Black sea. Sardines from other parts of the world differ from the European form in having a normal scale arrangement and consequently are placed in another genus, *Sardinops*, of which five species are recognized by some authorities. These are *S. melanosticta* of Japan, *S. caerulea* of the west coast of North America, *S. sagax* of the west coast of South America, *S. neopilchardus* of New Zealand and southern Australia and *S. ocellata* of South Africa. The differences among these species are so slight that certain authorities recognize only three of them, *S. sagax*, *S. melanosticta* and *S. neopilchardus*.

Pilchards associate according to size in dense schools or shoals, feed on minute pelagic organisms and grow to be 10 to 12 in. in length. The spawning season varies from species to species; among those of the northern hemisphere it occurs in spring and summer. The eggs are given forth into the open sea and are fertilized there. Suspended near the surface, they drift passively with the currents, hatch within a few days into larvae, which continue to drift passively until they metamorphose into free-swimming fish. Pilchards migrate extensively along the coasts they inhabit, those in the northern hemisphere moving north in summer and south in winter.

Pilchards are utilized for canning and for the manufacture of fish oil and fish meal, which is used for animal feeds. For these purposes about 2,000,000,000 lb. are caught annually in Japan and 1,000,000,000 lb. on the west coast of North America. In the Mediterranean, they are used principally for canning. In Cornwall, England, considerable quantities are salted. The name sardine is frequently used for other species of small herring-like fishes that are canned. (L. A. Wd.)

PILE. As a textile term, this word indicates the surface of a cloth composed of an infinite number of loops of warp threads, or else of an infinite number of free ends of either warp or weft (filling) threads that stand erect from the foundation or ground structure of the cloth. There are two general methods of distinguishing between such cloths; thus:—

1. When the loops are uncut, the pile is usually termed "looped pile."

2. When the same or similar loops are cut, either in the loom during weaving or by a special machine after the cloth leaves the loom, the pile is termed "cut pile."

Other names applied to such cut-pile fabrics in which the effect is formed by the *warp* threads are "velvet" and "plush," the former being used to define short-pile fabrics and the latter to define long-pile fabrics. The word "velveteen" is used to distinguish the fabric when the pile is formed of *weft* or filling threads that have been cut.

Among the loop-pile fabrics may be mentioned Brussels tapestry and imitation Brussels carpeting, as well as Moquettes and the like. In some cases the surfaces of carpets, such as Wilton and Axminster, are formed of cut pile; and again, both looped (uncut pile) and cut pile appear on the surface of the same fabric. Imitation sealskins and several other kinds consist of monocoloured pile, whereas all the above mentioned carpets have surfaces upon which decorative designs appear in both kinds of pile and in several colours. (See CARPET MANUFACTURE; RUGS AND CARPETS. For pile in building see FOUNDATIONS.) (T. W.)

PILGRIMAGE, a journey undertaken, from religious motives, to some place reputed as sacred. These journeys play an important role in most pre-Christian and extra-Christian religions: in the Catholic Church their acceptance dates from the 3rd and 4th centuries.

The Pilgrimage in Pre- and Non-Christian Religions.—To the Germanic religions the pilgrimage is unknown. On the other hand, it is an indigenous element, not only in the creeds of Asia, but in those of the ancient seats of civilization on the Mediterranean. The fundamental conception is always that the Deity resides—or exercises a peculiarly powerful influence—in some definite locality; and to this locality the devout repair, either in reverence of their god, or in quest of his assistance and bounty.

One of the oldest homes of the pilgrimage is India. There the devotees tend especially to the Ganges—the hallowed river of Hindu belief. On the Ganges lies Benares, the holy city of Brahmanism; and to look on Benares, to visit its temples, and to be washed clean in the purifying river, is the yearning of every pious Indian. Even Buddhism—originally destitute of ceremonial—adopted the pilgrimage; and the secondary tradition makes Buddha himself determine its goals: the place where he was born, where he first preached, where the highest insight dawned on him, and where he sank into Nirvana. The habit of religious expeditions to sacred places took deep root among the Egyptians, the Jews, and the Greeks; but the pilgrimage attained its zenith under Islam. For Mohammed proclaimed it the duty of every Mussulman, once at least in his life, to visit Mecca; the result being that the birthplace of the Prophet is the religious centre of the Mohammedan world. (See ISLAM; CARAVAN; MECCA.)

THE PILGRIMAGE UNDER CHRISTIANITY

The pilgrimages of Christianity presuppose the existence of those of paganism; but it would be an error to maintain that the former were a direct development of the latter. For primitive Christianity was devoid of any point by which these journeys of devotion might naturally have been suggested. It was a religion without temples, without sanctuaries, and without ceremonial. The

saying of the Johannine Gospel—that God is to be adored neither in Jerusalem nor on Gerizim, but that His true worshipper must worship Him in spirit and in truth—is in complete harmony with the old Christian piety. The Christian pilgrimage arose from devotion to the memory of Jesus; the faithful repaired to those places which were invested with memories of their Lord's earthly life. Bethlehem and Jerusalem became objects of such visits from the 2nd century; and from references in Eusebius and others, it is evident that the Christians of the 3rd and 4th centuries were in the habit of visiting Jerusalem for prayer; and that men travelled for purposes of prayer implies acceptance of the theory of sanctuaries which it is an act of piety to visit.

THE PILGRIMAGE IN THE ANCIENT CHURCH

The East.—In the passages cited above, Bethlehem and the Mount of Olives figure as the main goal of the pilgrim: and on the Mount of Olives the mind must naturally turn to the Garden of Gethsemane and the scene of the Ascension. It may seem surprising that there is no mention of Golgotha and the Sepulchre. But the visitation of these sites was rendered impossible to the Christians by the destruction of Jerusalem and the erection of the town of Aelia Capitolina. The one holy site in the town of Jerusalem, before the time of Constantine, was the so-called *Coenaculum*, which received its name in later years. It was regarded as the house in which—according to the Acts of the Apostles (xii. 12 *sqq.*)—Mary, the mother of John Mark, lived; and the belief was that there the Lord held the Last Supper, and that there the eleven assembled after the Ascension.

The pilgrimage to Palestine received a powerful impetus from the erection of the memorial churches on the holy sites, under Constantine the Great, as described by Eusebius in his biography of the emperor (iii. 25 *sqq.*). At the order of Constantine, the accumulation of rubbish covering the supposed site of the burial-place of Jesus was removed, and the cave was discovered in which Joseph of Arimathea had laid the body of Jesus; and above this cave and the Hill of the Crucifixion the imposing church of the Holy Sepulchre was built (A.D. 326–336). The churches in Bethlehem and on the Mount of Olives were erected by Helena, the mother of Constantine, who herself undertook the pilgrimage to the Holy Land. These churches were then endowed with new sanctuaries of miraculous powers; and relics of Christ were found in the shape of the Cross and the nails. The result was an exaggerated importance attached to these pilgrimages, a view which led to energetic protests, especially from Gregory of Nyssa, who composed a monograph on the pilgrimages (*De iis qui adeunt Hierosol.*). Jerome, like Gregory, insists on the point that residence in Jerusalem has in itself no religious value: it is not locality, but character, that avails, and the gates of Heaven are as open in Britain as in Jerusalem (*Ep.* 58, 3).

But Jerome never denied the religious uses of the pilgrimage; he considered it an act of faith for a man to offer his prayers where the feet of the Lord had stood, and the traces of the Birth, of the Cross, and of the Passion were still to be seen (*Ep.* 47, 2). With the number of the pilgrims the number of pilgrim-resorts also increased. Of Jerusalem alone Jerome relates that the places of prayer were so numerous that it was impossible to visit them all in one day (*Ep.* 46, 9). In the Holy Land the list was still longer: the natives were ready to show everything for which the foreigners inquired, and the pilgrim was eager to credit everything. In her expedition to the East, Paula, the friend of Jerome, visited, among other places, Sarepta and Caesarea. In the first-named place she was shown the tower of Elijah; in the second, the house of Cornelius, that of Philip, and finally the grave of the four virgins. At Bethlehem she saw, in addition to the church of the Nativity, the grave of Rachel; at Hebron the hut of Sarah, in which the swaddling clothes of Isaac and the remains of Abraham's oak were on view (*Hieron. Ep.* 108).

In the West.—While pilgrim-resorts were thus filling the East, their counterparts began to emerge in the West. And here the starting-point is to be found in the veneration of martyrs. Care for the tombs of martyrs was sanctioned by immemorial custom of the Church; but, in this case also, a later age failed to preserve

the primitive conception in its purity; and Augustine himself was obliged to defend the usage of the Church from the imputation that it implied a transference of heathen ceremonial to the sphere of Christianity (*Contr. Faust.* xx. 21). The martyrs were the local heroes of particular communities; but there were men whose life and death were of significance for the whole of Christendom—the apostles. Of these Peter and Paul had suffered martyrdom in Rome, and it was inevitable, from the nature of the case, that their graves should soon become a resort, not only of Romans born, but of strangers also. The Roman cemeteries were visited by numerous pilgrims even in the 3rd century: for the earliest graffiti in the papal crypt of the Coemeterium Callisti must date from this period (*De Rossi, Roma sotter.* i. 253 *sqq.*; *Kraus, Rom. Sott.* 148 *sqq.*).

Pilgrims were drawn to the graves of the saints convinced that there divine succour was certain; hence came the belief in a never-ending series of miracles there performed. Doubt was unknown. St. Augustine observes that, though Africa was full of martyrs' tombs, no miracle had been wrought at them so far as his knowledge extended. This, however, did not lead him to doubt the truth of those reported by others—a fact that is somewhat surprising when we reflect that the phenomenon caused him much disquiet and perplexity. Who, he asks, can fathom the design of God in ordaining that this should happen at one place and not at another? And eventually he acquiesces in the conclusion that God, who gives every man his individual gift at pleasure, has not willed that the same powers should have efficacy at every sepulchre of the saints (*Ep.* 78, 3).

THE PILGRIMAGE IN THE MIDDLE AGES

The mediaeval Church adopted the custom of the pilgrimage from the ancient Church. The young Germanic and Romance nations did precisely as the Greek and Romans had done before them, and the motives of these devotional journeys—now much more difficult of execution in the general decay of the great world-system of commerce—remained much the same. They were undertaken to the honour of God, for purposes of prayer, or in quest of assistance, especially health. But the old causes were reinforced by others of at least equal potency. The mediaeval Church was even more profoundly convinced than its predecessor that the miraculous power of Deity attached to the bodies of saints and their relics. But the younger nations—French, English and German—were scantily endowed with saints, while, on the other hand, the belief obtained that the home-countries of Christianity, especially Rome and Jerusalem, possessed an inexhaustible supply of these sanctified bodies.

Pilgrimages were consequently undertaken with the intention of securing relics. At first it was enough to acquire some object which had enjoyed at least a mere connection with the hallowed corpse. One enthusiast took a little wax dropped from the taper; another, a portion of the dust which lay on the grave; a third, a thread from the cloth covering the sarcophagus; still another plucked the flowers which visitors had planted above the tomb. Before long, however, these humble trophies failed to content the pilgrims, and they began to devote their efforts to acquiring the actual bodies, or portions of them—frequently by honest means, still oftener by trickery. One of the most attractive works of early mediaevalism—Einhard's little book, *Translatio Marcellini et Petri*—gives a vivid description of the methods by which the bodies of the two saints were acquired and transported from Rome to Seligenstadt on the Main.

Far more important consequences, however, resulted from the fact that the mediaeval mind associated the pilgrimage with the forgiveness of sins. This conception of the pilgrimage, as a means of expiation or a source of pardon for wrong, was foreign to the ancient Church. It is quite in accordance with the keener consciousness of sin, which prevailed in the middle ages, that the expiatory pilgrimage took its place side by side with the pilgrimage to the glory of God. The pilgrimage became an act of obedience; and, in the books of penance (*Poenitentialia*) which date from the early middle ages, it is enjoined as an expiation for many of the more serious sins, especially murder or the less venial forms of

unchastity. The place to be visited was not specified; but the pilgrim, who was bound by an open letter of his bishop to disclose himself as a penitent, lay under the obligation, wherever he went, to repair to the churches and—more especially—the tombs of the saints, and there offer his prayers. On occasion, a chain or ring was fastened about his body, that his condition might be obvious to all; and soon all manner of fables gained currency: how, here or there, the iron had sprung apart by a miracle, in token that the sinner was thereby absolved by God.

As the system of indulgences (*q.v.*) developed, a new motive came to the fore which rapidly overshadowed all others: pilgrimages were now undertaken to some sacred spot, simply in order to obtain the indulgence which was vested in the respective church or chapel. In the 11th century the indulgence consisted in a remission of part of the penance imposed in the confessional, in return for the discharge of some obligation voluntarily assumed by the penitent. Among these obligations, a visit to a particular church, and the bestowal of pious gifts upon it, held a prominent place; and during the whole period of mediaevalism, the number of pilgrims was perpetually on the increase.

The Pilgrim Resorts.—The most important places of resort both for voluntary and involuntary pilgrimages, were still Palestine and Rome. On the analogy of the old *Itinerario*, the abbot Adamnan of Iona (d. 704) now composed his monograph *De locis sanctis*, which served as the basis of a similar book by the Venerable Bede (d. 735). His authority was a Frankish bishop named Arculf, who resided for nine months as a pilgrim in Jerusalem, and visited the remaining holy sites of Palestine in addition to Alexandria and Constantinople. Of the later itineraries the *Descriptio terrae sanctae*, by the Dominican Burchardus de Monte Sion, enjoyed the widest vogue. This was written between the years 1285 and 1295; but books of travel in the modern tongues had already begun to make their appearance. The initiative was taken by the French in the 12th and 13th centuries, and the Germans followed in the 14th and 15th; while the *Book of Wayes to Jerusalem* of John de Maundeville (*c.* 1336) attained extreme popularity, and was translated into almost all the vernacular languages.

As a result of this steady increase in the number of pilgrims, the old arrangements for their accommodation were found deficient. Consequently hospices arose which were designed exclusively for the pilgrim. Those on the Alpine passes are common knowledge. The oldest, that on the Septimer pass, dates from the Carolingian period, though it was restored in 1120 by the bishop Wido of Chur: that on the Great St. Bernard was founded in the 10th century, and reorganized in the 13th. To this century may also be assigned the hospice on the Simplon; to the 14th those on the St. Gothard and the Lukmanier. Similarly, the Mediterranean towns, and Jerusalem in particular, had their pilgrim-refuges. Service in the hospices was regularly performed by the hospital-fraternities—that is to say, by lay associations working under the authorization of the Church. The most important of these was the fraternity of the *Hospitale hierosolymitanum*, founded between 1065 and 1075; for hence arose the order of St. John, the earliest of the orders of knighthood. (See ST. JOHN OF JERUSALEM, KNIGHTS OF.) In addition to the hospital of Jerusalem, numerous others were under its charge in Acre, Cyprus, Rhodes, Malta, etc. Associations were formed to assist pilgrims bound for the East; one being the *Confrérie des pèlerins de Terre-Sainte* in Paris, founded in 1325 by Louis de Bourbon, count of Clermont (afterwards first duke of Bourbon).

But since, in the middle ages, the Holy Land was no longer held by a Christian Power, the protection of the pilgrims was no less necessary than their sustenance. This fact, after the close of the 11th century, led to the Crusades (*q.v.*), which in many respects are to be regarded as armed pilgrimages. For the old dream of the pilgrim, to view the country where God had walked as man, lived on in the Crusades—a fact which is demonstrated by the letters of Bernard of Clairvaux, with the songs of Walther von der Vogelweide and other Crusaders. And, since the strongest motive in the pilgrimage was the acquisition of indulgences, unnumbered thousands were moved to assume the Cross, when, in

1095, Urban II. promised them plenary indulgence. The conquest of Jerusalem, and the erection of a Christian empire in Palestine, naturally swelled the influx of pilgrims. And though in 1187 the Holy City again fell into the hands of the infidel, while in 1291 the loss of Acre eliminated the last Christian possession in Palestine, the pilgrimages still proceeded. It was not till the Reformation, the wars of the 16th century, and the loss of Rhodes, Candia and Cyprus to the Turks, that any appreciable alteration was effected. When Ignatius de Loyola (*q.v.*) set sail in 1523 from Venice to Palestine, only some thirteen souls could be mustered on the pilgrim-ship, while eight or nine others sailed with the Venetian state-vessel as far as Cyprus. A considerable number had abandoned their pilgrimage and returned home on the news of the fall of Rhodes.

For pilgrimage overseas, as it was styled, the permission of the Church was still requisite. The pilgrims made their journey in grey cowls fastened by a broad belt. On the cowl they wore a red cross; and a broad-brimmed hat, a staff, sack and gourd completed their equipment. During their travels the beard was allowed to grow, and they prepared for departure by confession and communion. Of their hymns many are yet extant ("Jerusalem mirabilis," "In gottes namen faren wir," etc.). Ships belonging to the knights of St. John and the Knights Templars conducted the commerce with Palestine, and the pilgrims formed themselves into unions, elected a "master" and concluded their agreements, as to the outward voyage and return, in common. The expenses of the journey to Palestine were no light matter. In the 12th century they may be estimated at 100 marks of silver (£200) for the ordinary pilgrim. The expenses of the princes and lords were, of course, much heavier. Duke William of Saxony, who was in Jerusalem in 1461, spent no less than £10,000 on his journey. (See Prutz, *Kulturgeschichte der Kreuzzüge*, pp. 106 sqq.; Röhrich, *Deutsche Pilgerreisen*, p. 42.)

Great as was the number of pilgrims overseas, it was yet far exceeded by that of the visitants to the "threshold of the apostles," i.e., Rome, which received their greatest impetus through the inauguration of the so-called Year of Jubilee.

Of the other pilgrim-resorts, we shall only emphasize the most important. Priority of mention is due to St. James of Compostela (Santiago, in the Spanish province of Galicia). Here the attraction for the pilgrim was the supposed possession of the body of James the son of Zebedee. The first connection of the apostle with Spain is to be traced in the *Poema de aris b. Mar. et xii. apost. dedic.*, which is ascribed to Aldhelm (d. 709) and contains a story of his preaching in that country. The earliest account of the transference of his relics to the Peninsula is found in Notker Balbulus (d. 912, *Martyrol. in Jul. xxv.*). But in Spain belief in this cherished possession was universal; and, step by step, the theory won credence throughout the West. In England, indeed, the shrine of St. James of Compostela became practically the most favoured devotional resort; and in the 12th century its visitation had attained such popularity that a pilgrimage thither was ranked on a level with one to Rome or Jerusalem. In France St. Martin remained the chief goal of the pilgrim; while Notre Dame de Sous-Terre in Chartres (with a portrait of the "black Virgin"), Le Puy-en-Velay (dep. Haute Loire), and others, also enjoyed considerable celebrity. In England pilgrimages were made to the tomb of the murdered archbishop, Thomas à Becket, in Canterbury Cathedral. The setting of Chaucer's *Canterbury Tales* gives a vivid idea of the motley company of pilgrims; but it seems probable that Germany also sent a contingent. In addition, Walsingham, Peterborough, St. Davids, Holywell, and St. Andrews in Scotland were much frequented. In lower Germany, Cologne and Aix-la-Chapelle, in Switzerland Einsiedeln, were the principal resorts.

In Italy the church of the Archangel on Mt. Gargano was one of the most ancient centres of the pilgrimage. Later the Portiuncula church at Assisi displaced all other resorts, with the exception of Rome; but in the 15th century it was overshadowed in turn by the "Holy House" at Loretto on the Adriatic. According to an extravagant legend, the house of Joseph and Mary in Nazareth was transported by angels, on the night of the 9th-10th of May

1291 to Dalmatia, then brought to the Italian coast opposite (Dec. 10, 1294), till, on the 7th of September 1295 it found rest on its present site. The pilgrimage thither must have attained great importance as early as the 15th century; for the popes of the Renaissance found themselves constrained to erect an imposing pilgrim church above the "Holy House."

The significance of the pilgrimage for the religious life of later mediaevalism cannot be adequately estimated. The possession of any extraordinary relic was everywhere considered a sufficient claim for the privileges of indulgences; and wherever this privilege existed, there the pilgrims were gathered together. All these pilgrimages, great and small, were approved and encouraged by the Church. And yet, during the whole of the middle ages, the voice of suspicion in their regard was never entirely stilled. Earnest men could not disguise from themselves the moral dangers almost inevitably consequent upon them; they recognized, moreover, that many pilgrims were actuated by extremely dubious motives; and they distrusted the exaggerated values set on outward works. The Roman papacy had no more zealous adherent than Boniface; yet he absolutely rejected the idea that Englishwomen should make the journey to Rome, and would willingly have seen the princes and bishops veto these pilgrimages altogether (*Ep.* 78). The theologians who surrounded Charlemagne held similar views.

When the abbess Ethelburga of Fladbury (Worcestershire) found her projected pilgrimage impracticable, Alcuin wrote to her, saying that it was no great loss, and that God had better designs for her: "Expend the sum thou hast gathered for the journey on the support of the poor; and if thou givest as thou canst, thou shalt reap as thou wilt" (*Ep.* 300). Bishop Theodulf of Orleans (d. 821) made an energetic protest against the delusion that to go to Rome availed more than to live an upright life (*Carm.* 67). To the same effect, the synod of Chalon-sur-Saône (813) reprobated the superstition which was wedded to the pilgrimage (*c.* 13); and it would be easy to collect similar judgments, delivered in every centre of mediaevalism. But, fundamentally, pilgrimages in themselves were rejected by a mere handful: the protest was not against the thing, but against its excrescences.

The Modern Pilgrimage.—The Reformation eradicated the belief in the religious value of visits to a particular locality. It is only pious memory that draws the Protestant to the sites consecrated by ecclesiastical history. On the other hand, while in the Eastern Church things have undergone little change the developments in the Roman Church show important divergences. The Year of Jubilee, in 1525, was unprecedented in its scant attendance, but the jubilees of 1575 and 1600 again saw great armies of pilgrims marching to Rome (*see* JUBILEE YEAR). Fresh pilgrim resorts sprang up; mediaeval shrines, which had fallen on evil days, emerged from obscurity. The 19th century led to an extraordinary revival of the pilgrimage. Not only did new resorts spring into existence—e.g., La Salette in Dauphiné (1846), and more particularly Lourdes (1858) in the department of Hautes Pyrénées—but the numbers once more attained a height which enables them to compete with the mediaeval figures. The dedication of the church of Lourdes, in 1876, took place in the presence of 30 bishops, 3,000 priests and 100,000 pilgrims. No new motives for the pilgrimage emerged in the 19th century, unless the ever-increasing cultus of the Virgin Mary may be classed as such, all of the new devotional sites being dedicated to the Virgin. For the rest, the desire of acquiring indulgences maintains its influence: but doubting voices are no more heard within the pale of the Roman Catholic Church.

PILGRIM FATHERS. In American history "Pilgrims" is applied to the earliest settlers of the colony of Plymouth, Mass., and its more specific application is to the first emigrants, who sailed in the "Mayflower" in 1620. They were from the beginning Separatists from the Church of England; they had established Independent (Congregational) churches at Scrooby and Gainsborough early in the 17th century, and some of them had fled to Amsterdam in 1608 to avoid persecution, and had removed to Leyden in the following year. They sailed from Delftshaven late in July 1620, from Southampton on Aug. 5, from Plymouth on Sept. 6 and late in Dec. 1620 founded the colony of Plymouth, Massachusetts. (*See* MASSACHUSETTS; PLYMOUTH and MAYFLOWER.)

PILGRIMS' WAY, THE. From Winchester, in Hampshire, England, to Canterbury, in Kent, runs a road or way which can still be traced, now on the present made roads, now as a lane, bridle path, or cart track, now only by a line of ancient yews, hollies or oaks which once bordered it. To this old track the name of Pilgrims' Way has been given, for along it passed the stream of pilgrims coming through Winchester from the south and west of England and from the continent of Europe by way of Southampton to Canterbury Cathedral to view the place of the martyrdom of Thomas Becket, in the north transept, the relics in the crypt where he was first buried after his murder, in 1170, and the shrine in the Trinity Chapel which rose above his tomb after the translation of the body in 1220. There were two festivals for the pilgrimage, on the 29th of December, the day of the martyrdom, and on the 7th of July, the day of the translation. The summer pilgrimage naturally became the most popular. In 1538 the shrine was destroyed and the relics of the saint scattered, but the great days of the pilgrimage had then passed. Erasmus gives a vivid picture of the glories of the shrine and of all that the pilgrims saw on his visit with Colet to Canterbury in 1514.

This road, although its name of the Pilgrims' Way has for long confined it to the road by which the pilgrims came to Canterbury from Winchester, follows a far older track. Right back into British and even older times the main direction which commerce and travellers followed across southern and western England to the Straits of Dover and the Continent lay from Canterbury along the southern chalk slope of the North Downs to near Guildford, then by the Hog's Back to Farnham. At this point the oldest track went across Salisbury Plain towards Stonehenge and so on to Cornwall. From Farnham westward the only portion of this, the oldest track that can now be traced, is a small portion that still bears the name of the Harrow (*i.e.*, hoary, old) road. It was in early times abandoned for the road from Winchester to which the stream of travel and commerce from the Continent and the south and south-west of England was diverted.

The ancient road has been traced fully in Mrs. Ady's book *The Pilgrims' Way* (1893), and the older track in the fullest detail in Hilaire Belloc's *The Old Road* (1904).

PILKINGTON, FRANCIS (d. 1638), English madrigal composer, the details of whose early life are obscure, took his Mus.B. at Lincoln college, Oxford. He was attached to Chester cathedral about 1604, and a few years later was ordained. His chief works include a book containing 21 vocal pieces and a pavin for the lute and bass viol (1605), *The First Set of Madrigals and Pastorals* (1614), and *The Second Set of Madrigals and Pastorals* (1624).

PILLAU, a seaport and watering-place in the Prussian province of East Prussia, on the spit of sand (*Nehrung*) which separates the Frische Haff from the Baltic, on the north of the entrance channel, and 29 m. by rail from Königsberg. Pop. (1933) 7,092. Pillau is the place where Gustavus Adolphus of Sweden landed in 1626. It did not obtain civic privileges until 1725, but was fortified shortly after that date. It has a harbour, which serves as the outer port of Königsberg, and to some extent also of Elbing and Braunsberg. A new navigable channel was in 1900-1901 constructed across the Frisches Haff from Pillau to Königsberg. Pillau has a school of navigation, and is a well-known pilot station. Ship-building and fishing are carried on.

PILLNITZ, a German village in the *Land* of Saxony, on the right bank of the Elbe, 5 m. above Dresden. Pop. (1933)

1,231. The new palace was built in 1818 on the site of a building which was burnt. The place became a residence of the electors of Saxony about 1700. By the convention of Pillnitz in August 1791 the emperor Leopold II. and Frederick William II., king of Prussia, agreed to take common action against any attack on the part of France.

PILLORY, an instrument of punishment which consisted of a wooden post and frame fixed on a platform raised several feet from the ground, behind which the culprit stood, his head and his hands being thrust through holes in the frame (as are the feet in the stocks) so as to be held fast, exposed in front of it. This frame in the more complicated forms of the instrument consisted of a perforated iron circle, which secured the heads and hands of several persons at the same time, but it was commonly capable of holding only one.

In the statutes of Edward I. it is enacted that every pillory or "stretch-neck" should be made of convenient strength so that execution might be done on offenders without peril of their bodies. It was customary to shave the heads wholly or partially, and the beards of men, and to cut off the hair and even in extreme cases to shave the heads of female culprits. By the "Statute of the Pillory" (1266) the pillory was made the penalty for many small offences. In 1637 an attack was made on the Press, and the pillory became the recognized punishment of those who published books without a licence or libelled the Government. In 1816 the pillory was abolished except for perjury and subornation, and the perjurer Peter James Bossy was the last to stand in the pillory, at the Old Bailey for one hour on June 22, 1830. It was finally abolished in 1837 at the end of William IV.'s reign. In France the pillory, called *carcan*, was employed till 1832. In Germany it was known as *pranger*. The pillory was used in the American colonies, and provisions as to its infliction existed in the U.S. statute books until 1839; it survived in Delaware until 1905. (See STOCKS.)

PILNYAK, the pseudonym adopted by the Russian novelist BORIS ANDREYEVICH VOGAU (1894-?). Born on Sept. 29, 1894, at Mozhaisk in the province of Moscow, Pilnyak spent his early youth on the Volga and among peasants or with the intellectuals of the land administration. He began to publish stories in 1915. He was in Moscow during the Bolshevik revolution, travelled subsequently through Russia studying the new conditions and visited England and Germany in 1923. His works, which deal with the first chaotic stage of transition from the tsarist regime to that of the soviets, make him one of the most prominent figures in post-revolutionary Russian fiction; his manner and style were much influenced by the novels of Andrei Byeluy. Among his books are: *The Naked Year* (1922), *Ivan and Maria* (1923), *English Tales* (1924), *Machines and Wolves* (1925), *Time Diffused* (1927), *Mahogany* (Berlin, 1929; banned in the U.S.S.R.), *The Volga Pours Into the Caspian* (1930) and *O.K.* (1933; impressions of America). He is said to have been sent to Siberia and shot.

PILOCARPINE, an alkaloid which occurs in *Jaborandi* leaves together with a stereoisomer, isopilocarpine and pilosine, $C_{16}H_{18}N_2O_3$. Pilocarpine, $C_{11}H_{16}N_2O_3$, was isolated independently by E. Hardy and by A. W. Gerrard in 1875. It melts at $34^\circ C.$, but is usually obtained as a colourless oil, boiling at $260^\circ C.$ at 5 mm. pressure, soluble in water, alcohol or chloroform, almost insoluble in ether, dextrorotatory in solution. Knowledge of its structure is largely the result of the work of H. A. D. Jowett (England) and of A. Pinner (Germany). It consists of a lactone ring and an imidazole nucleus, joined by a CH_2 group, and was synthesized (as was also isopilocarpine) by N. A. Preobrazhenski in 1933. The crystalline nitrate and other salts are used to promote sweating and salivation, and externally to cause miosis. (L. F. St.)

PILONA, a town of northern Spain on the Infiesto-Oviedo railway in the province of Oviedo; between the right bank of the river Piloña, a left-hand tributary of the Sella, and the Sierra de Abes (3,268 ft.). Pop. (1940) mun., 16,948. Piloña is a densely populated mining and agricultural district.

PILOTAGE, as it is now understood, may be described as the art of conducting a vessel in or out of harbour, or in the neighbourhood of navigational dangers. The word "pilot" was formerly used to designate the steersman and later the sailing

master; in fact, the art of piloting was divided into two parts: proper piloting, identical with what we now term navigating (see NAVIGATION), and common piloting, identical with the meaning of the word as given above. See PILOTAGE LAWS.

PILOTAGE LAWS. The present general British pilotage laws are contained in the Pilotage Act, 1913, which Act consolidated and amended the laws of pilotage as they existed under the Merchant Shipping Act, 1894. On the passing of the former Act, the Board of Trade, as the central authority, held enquiries, with the result that pilotage orders were made by it in respect of each District. Each pilotage order defines the limits of the district, names the pilotage authority therefor, states whether pilotage is compulsory or not therein, and empowers the authority to delegate any of its powers or duties to a pilotage committee, on which may sit representatives of both pilots and shipowners. The pilotage authority makes the necessary by-laws for the regulation of pilotage and pilots in its district, but these do not take effect until they are confirmed by the Board of Trade.

The principal pilotage authority is the Corporation of Trinity House, London, exercising jurisdiction in the London district, which extends from Orfordness to Selsea Bill, and in 38 other districts round the coasts of England and Wales. There are, however, about 60 other districts within which other pilotage authorities have jurisdiction.

Compulsory Pilotage.—A ship, whilst navigating in a district in which pilotage is compulsory, for the purpose of entering, leaving or making use of any port in that district, is required to be either under the pilotage of a licensed pilot of the district, or under the pilotage of a master or mate possessing a pilotage certificate for the district, who is bona fide acting as master or mate of the ship. A ship carrying passengers (other than an excepted ship) is, however, compelled to be under pilotage irrespective of whether the district in which she is navigating is a compulsory one or not. Under the Aliens Restriction (Amendment) Act, 1919, pilotage certificates cannot be granted to aliens, except to masters or mates of French nationality trading to the ports of Newhaven or Grimsby.

The following ships are excepted from compulsory pilotage: (1) Ships belonging to His Majesty. (2) Pleasure yachts. (3) Fishing vessels. (4) Ferry boats. (5) Ships of less than 50 tons' gross tonnage. (6) Ships exempted by by-law. (7) Tugs, dredgers, sludge vessels, barges and other similar craft belonging to or hired by a dock, harbour or river authority. (8) Ships calling at a port in a pilotage district for the sole purpose of taking on board or landing a pilot belonging to some other pilotage district.

The Board of Trade has the power, on the representation of parties interested, to revoke or vary any by-laws in a pilotage district, or require the pilotage authority to make by-laws. The licensing of a pilot by a pilotage authority does not involve any liability on the part of the authority for any loss occasioned by any act or default of the pilot.

Pilot Boats.—All pilot boats regularly employed in any district must be approved and licensed by the pilotage authority for that district, who may appoint or remove the masters thereof. Every pilot boat must be distinguished by the name of her owner and port on her stern, and her number on each bow, and the hull of the boat is usually painted black. When afloat the pilot boat must fly a red and white horizontal flag, known as a pilot flag, in a conspicuous position. A pilot flag must also be displayed by a vessel having on board a licensed pilot for the district, or a master or mate holding a pilotage certificate. The master of a ship subject to pilotage in a district must, under a penalty, display a pilot signal and keep it displayed until a licensed pilot comes on board, and if the master accepts the services of a pilot he must give him facilities for getting on board.

The following persons are liable to pay pilotage dues for any ship for which the services of a licensed pilot have been obtained, viz.: (a) the owner or master, or (b) the consignees or agents who have paid or are liable to pay any other charges on account of the ship, and these dues may be recovered in the same manner as fines under the Merchant Shipping Act, 1894. The pilotage dues on foreign ships, subject to compulsory pilotage, trading to and from

the port of London, have to be paid to the chief officer of customs and excise in that port, and such a ship may be detained until such dues are paid. It is an offence, punishable by a fine, if a licensed pilot demands or receives, and a master offers or pays, dues in respect of pilotage services at any other rates, whether greater or less, than those which are fixed by by-law.

Under section 633 of the Merchant Shipping Act, 1894, the owner or master of a ship was not answerable to any person for any loss or damage occasioned by the fault or incapacity of any qualified pilot acting in charge of that ship within any district where the employment of a qualified pilot was compulsory by law. Section 15 of the Pilotage Act, 1913, however, reversed this defence of compulsory pilotage, and enacted that the owner or master of a vessel navigating under circumstances in which pilotage is compulsory is answerable for any loss or damage caused by that vessel, or by any fault of her navigation, in the same manner as he would if pilotage were not compulsory. Section 15 of the Pilotage Act, 1913, did not, however, come into effect until Jan. 1, 1918, on which date section 633 of the 1894 Act was repealed. The difference which formerly existed under the Merchant Shipping Act, 1894, between British law and the law of most foreign countries as to the civil liability of the owner or master of a vessel employing a pilot under compulsion of law has therefore been removed since Jan. 1, 1918.

See *The Pilotage Act, 1913; Report of Departmental Committee on Pilotage 1911; Digby & Cole, Pilotage Law (1913).* (W. J. T. H.)

UNITED STATES

The power of administering all matters relating to pilotage was acquired by the Federal Government as incidental to the authority conferred on it under the Constitution. The first legislative action of the new Government was in 1789, when it delegated its authority to the several States "until further provision is made by Congress." Further legislation enacted subsequently has restricted the broad powers conferred in 1789, but the power of the Federal Government is exclusive only when it is exercised. State laws regarding pilotage are operative so long as they are not in conflict with Federal laws.

Among the acts of the Federal Government restricting the manner in which the several States may control pilotage are: laws which apply to pilotage on waters that are boundaries between States, permitting the master of a vessel to employ a pilot licensed by either State to pilot the vessel to or from such port; laws which prohibit discrimination in rates or pilotage as between vessels operating solely between ports in the State and those engaged in interstate traffic; laws which provide that all coastwise seagoing steamships shall be under the control and direction of pilots licensed under Federal authority; and laws which prohibit State pilots from levying pilotage on coastwise seagoing steamships.

Number and Appointment of Pilots.—In many States no maximum or minimum restriction is placed by statute on the number of pilots that may be appointed, the number being left to the discretion of the several pilotage authorities. In some cases both a maximum and minimum number are prescribed by law and in other States only a maximum number is mentioned. As a rule pilots are licensed by the local pilotage authority, but in several States they are appointed by the governor. In a majority of the States, pilots are licensed for life and lose their licences only because of negligence, incapacity, misconduct or infirmity. In the remaining States licences are granted for periods of one to four years and are renewable. Several grades of licences are generally issued, the grade varying with the draft of vessel which the holder of the licence is considered competent to conduct.

Qualification of Pilots.—In all States the primary qualification for appointment as pilot is actual experience in piloting vessels. A number of States require that applicants for licences as pilots must have served an apprenticeship of a specified number of years on boats of the pilots' association, either in accordance with the law of the State or by regulation of competent authority.

Authority.—In the United States, a pilot occupies the status of an officer of the ship when on board in the exercise of his duty,

and his orders as such must be obeyed by the crew. When the master is on board, the orders of the pilot are considered to be those of the master's. The pilot is subject to the master in the matter of discipline but is not liable to any ship's duty except that of pilot. Once in charge of a vessel at sea, it is the duty of the pilot to stay by the ship until she reaches her destination or some place of safety, unless he is earlier discharged.

Liability of Pilots.—Pilots are generally required to give bond, usually \$500, to secure the faithful performance of their duties and for the payment of all damages that may accrue from their negligence, unskillfulness or unfaithfulness. The bond is not required in some States, the amount is not specified in the laws of others and in still others it is fixed. The courts have held that while a pilot is responsible to the owner of a vessel for negligence or default in the performance of this duty, he is not liable for the vessel's loss when he has used his best skill and judgment, although the result shows that his best judgment was wrong.

Compulsory Pilotage.—Pilotage is generally compulsory upon certain vessels, or classes of vessels, approaching or departing from a harbour. Throughout the States, all public vessels of the United States and all steamships engaged in the coasting trade are exempt from compulsory pilotage. In respect to other vessels or classes of vessels there is wide variation in the laws of the several States. In the great majority of States compulsory pilotage is prescribed for all vessels, both of domestic and foreign registry, engaged in foreign trade, but not for any class of vessel in the domestic trade. In general the rule is that there has been a tender of the services of a pilot if there has been displayed the customary pilot signal on the usual cruising ground of pilot boats at sea, and there is a visible approach of the boat towards the incoming vessel. If the offer of pilot service is refused, the pilot becomes entitled to full fees or half pilotage, according to the local State law, and the liability for payment is enforceable in admiralty.

Compensation.—In general, pilotage fees are fixed by statute, based on the draught of the vessel. In some cases the rates are prescribed by the local pilotage authorities and the net tonnage of the ship is a factor in determining the pilotage charges. In a number of States where pilotage is compulsory, the full rate is not charged if the services of a pilot are refused. The various statutes commonly provide that pilotage fees are to be paid by and are recoverable from the master or owners of the vessel. In addition to fees for the actual work of pilotage, the statutes of practically every State permit certain extra charges to be made to cover loss of time occasioned by detention of vessel in quarantine or by carrying the pilot to sea when the pilot boat was ready to take him off.

Pilot Boats.—The days when a large number of sailing vessels were in the pilot service off the principal ports, each vessel owned and operated independently, have given way. In 1929 at practically every large port in the United States all of the licensed pilots belong to an association, owning and operating one or more specially constructed steamers which are maintained on the pilotage grounds, usually at the bar. These grounds are well known to mariners, who may safely count on finding there at practically all times a pilot boat displaying the Union Jack, with a sufficient number of pilots aboard to accommodate any reasonable number of vessels seeking to enter the port.

BIBLIOGRAPHY.—For legislation on pilotage in the United States, see the Revised Statutes and the Statutes at Large of the United States, and the statutes of the several States in which pilot service is maintained, particularly Title 46, U.S. Code; Laws of 1909, New York, Ch. 42, Sec. 56; Revised Laws of Mass., 1902, as amended; Civil Code of 1906, California, Sec. 2036. (C. M. A.)

PILOT-FISH (*Naucratus ductor*), a pelagic fish of the family of horse-mackerels or Carangidae, well known to sailors from its habit of keeping company with ships and large fishes, especially sharks. It occurs in all tropical and subtropical seas, and is common in the Mediterranean. In summer pilot-fish accompany ships into port as far north as the south coast of England. It accompanies both ships and sharks on account of the supply of food which it derives from them, as does the remora (*q.v.*). All observers agree that, except in confinement, neither

the pilot-fish nor the sucking-fish is ever attacked by the shark. The pilot attains to a length of about 12 in. A sharp keel runs along the middle of each side of the tail. The teeth are small, arranged in bands. On a bluish ground-colour, five to seven dark-blue or violet cross-bands traverse the body from back to belly. The pilot-fish spawns in the open sea.

PILOTY, KARL VON (1826–1886), German painter, born at Munich, on Oct. 1, 1826, was the son of Ferdinand Piloty (d. 1844), noted as a lithographer. His picture of "Seni at the Dead Body of Wallenstein" (1855) soon gained for the young painter the membership of the Munich Academy, where he succeeded Schorn (his brother-in-law) as professor. He also executed a number of mural paintings for the royal palace in Munich. For Baron von Schach he painted the justly celebrated "Discovery of America." In 1874 he was appointed keeper of the Munich Academy, being afterwards ennobled by the king of Bavaria. Piloty was the foremost representative of the realistic school in Germany. He was a successful teacher, and among his more famous pupils may be mentioned Makart, Lenbach, Defregger, Max and Grützner. He died at Munich on July 21, 1886.

PILSEN or **PLZEN**, the second town of Bohemia at the confluence of the Radbuza and Mze in a fertile and productive fruit and cereal basin. The vicinity is rich in coal and iron. The staple product is beer, exported to all parts of the world, which is closely followed by iron and steel goods and machinery, mainly from the Skoda factory; spirits, leather goods, paper and earthenware are also produced in large quantities. The town is the trade and transport centre for the whole of southwest Bohemia and its cereal and cattle markets are famous. It was occupied by Germany in March 1939.

Little is known of Pilsen till the 10th century and it did not become a town till 1272 but since then it has figured largely in Bohemian history and was a centre of Catholic resistance during the Hussite wars. Among its sights are the 13th century Gothic church with a tower 325 ft. high and a 16th century Renaissance town hall. Pop. (1930) 114,150.

PILSUDSKI, JOSEPH (1867–1935), Polish soldier and statesman, was born in Nov. 1867 in Zulow (Zulowo), County of Wilno (Wilno) of an ancient family tracing their origin from the Lithuanian Princes of Ginet, and educated at Wilno and Kharkov.

In 1887 Pilsudski was involved in an anti-Tsarist plot and sentenced to five years' penal servitude in Eastern Siberia, although the trial clearly established his innocence and his deprecation of terrorist methods. He returned to Wilno in 1892 and formed the Polish Socialist party (P.P.S.). In 1894 he began the *Robotnik* (The Workman), a secret paper of radical tendencies, edited, printed and distributed by Pilsudski himself. He was already a force. His courage, keen sense of humour, attractive personality and good breeding made him the idol of the working classes; he was revered by the intelligentsia for the tenacity of his convictions, for his fearlessness and his iron will.

His activities increased rapidly. Armed resistance against atrocities of the Russian government was introduced into the party programme. Armed detachments of workmen protected meetings and demonstrations against the police and military, and bloodshed became frequent. In 1900 Pilsudski and his wife, Marie Tuszkiewicz, whom he had married in 1894, were arrested in the offices of the *Robotnik* in Łódź and for a year he was kept in a special cell in the notorious "Tenth Pavilion" of the Warsaw Citadel. Simulating insanity, Pilsudski was transferred to the St. Nicholas Hospital in St. Petersburg, where his friends rescued him by an ingenious plot on May 13, 1901. He lived in London for some time following his escape from imprisonment and returned to Cracow in 1902.

During the Russo-Japanese war Pilsudski planned an insurrection. Frustrated through lack of munitions, he visited Japan to enlist her support, but again proved unsuccessful. After the Russian revolution of 1905 and the convocation of the Duma Polish revolutionary activities were discontinued, but the Russian Constitutional government continued the policy of its predecessors with regard to Poland. Pilsudski transferred his headquarters to Cracow and Lwow and commenced his activities

amongst the refugees from the Russian provinces of the country. Here the idea of a "private Polish army" was conceived. An officers' school was established in Lwow and branches of the "sharpshooters" (Strzelec) formed throughout Galicia. Foreseeing the World War, Pilsudski hoped for a German and Austrian victory over Russia and a French victory over Germany. When war broke out, he consequently sided with Austria. The total strength of his "army" was 3,000 infantry and a squadron of cavalry insufficiently armed and equipped; the remaining 7,000 of his men were despatched to Hungary by the Austrian general command. His brigade took part in numerous battles in which it exhibited great bravery and exemplary discipline, while Pilsudski himself displayed the highest qualities as a leader. He refused, however, to let his legions be used outside of Polish territory. On the collapse of Russia, he turned against Germany and Austria. In July 1916 he resigned the command of the Polish legions in consequence of the abuses of the German and Austrian occupation authorities in Polish territory. At the same time he sought to establish relations with France and Great Britain through his colleagues, MM. Sokolnicki and Narutowicz. On Nov. 5, 1916, the independence of Poland was proclaimed by the Central Powers and Pilsudski accepted the position of Minister of War in the newly formed Council of State. Within a short time he formed the semi-secret Polish military organization, *i.e.*, *Polska Organizacja Wojskowa* ("P.O.W."), which spread throughout the country and helped to disarm Germans and Austrians in 1918.

When the Polish legions in Russia, commanded by Gen. Musnicki, proclaimed Pilsudski their spiritual leader, and when his own legions refused, in July 1917, to take the oath of "fraternity of arms with Germany and Austria," Pilsudski was arrested by the Germans and imprisoned with his chief-of-staff Gen. Sosnowski in the fortress of Magdeburg, whence he was released in 1918 by the German revolutionary authorities. He arrived in Warsaw on Nov. 10 and completed the disarmament of the armies of occupation. The Regency Council, established by the Germans, resigned in his favour and all military organizations in the country submitted to his command. He was vested with dictatorial powers, and elected unanimously chief of State, while the army conferred on him the supreme honour of first marshal of Poland.

For Pilsudski's activities during the next years, *see* POLAND. His own chief interest was centred in the army, with which he was very popular, and at the head of which he undertook the campaigns of 1920 in the Ukraine and against the Russian advance on Warsaw. He had, however, many difficulties with other elements in the State and in 1923 he ceased to be chief of State and retired altogether from the army. In May 1926, however, his notorious dislike of the typically-Polish parliamentary wrangling and faction recalled him. He put himself again at the head of the army; a military demonstration on May 12 led to fighting in Warsaw and the resignation of the president. The national assembly, convoked by his successor, M. Rataj, elected Pilsudski president (May 31); but he refused the honour, and became only minister of war, while his friends MM. Mosćicki and Bartel were elected respectively president and premier. Pilsudski immediately carried through legislation greatly strengthening the position of the president against the parliament; but did not dissolve the latter or establish an open dictatorship, although he constantly prorogued it. In September, indeed, he took over the premiership himself; but seldom appeared in the Sejm, even when it was sitting. The elections of March 1928 gave his adherents a majority. Nevertheless Pilsudski, who had been in bad health, resigned the premiership, retaining, however, the ministry of war, chairmanship of the army council and inspectorate-general of the force. This change made little difference to his position in Poland and the vigorous abuse of the Sejm with which he motivated his actions was not actively resented. He was again premier in 1930. For the events of his real, though veiled dictatorship, *see* POLAND. *See* also R. Landau, *Pilsudski and Poland* (1929).

PIMA, a tribe of Indians on Gila and Salt rivers in southern Arizona, closely related to the Papago, who adjoin them on the south, and to the Pima Bajo in Sonora. They practised irrigation

and lived in permanent though rudely built villages. In their territory are the adobe ruins of Casa Grande and miles of prehistoric ditches. They are divided into five patrilineal totemic groups, make fair pottery and excellent basketry. They differ much from the other sedentary and agricultural natives of the south-west, the Pueblos. Consistently friendly to the whites, they long withstood the Apache courageously, fought back the hostile Yuman tribes, and sheltered those that took refuge with them. Estimated at 2,500 in 1775, they numbered 5,100 in 1921. See F. Russell, *Bur. Am. Ethn. Rep.* xxvi. (1908).

The Piman or Sonoran family, now recognized as a division of the larger Uto-Aztecan one, extended from Arizona to Jalisco, Mexico, and included the Pima, Papago, Opata, Tarahumare, Mayo, Yaqui, Tepehuane, Tepecano, Cora, Huichol and other groups.

(A. L. K.)

PIMPERNEL (*Anagallis arvensis*), a small herb of the primrose family (Primulaceae), called also shepherd's clock and poor man's weather-glass, native to Europe and widely naturalized in North America from Newfoundland to the Pacific coast and southward to Mexico. It is a delicate annual with diffusely branching stems, with small, opposite, somewhat clasping, leaves, black-dotted beneath, and scarlet (rarely white) flowers, about $\frac{1}{4}$ in. across, usually with a darker centre, opening only in bright sunshine, whence numerous popular names.

PIN, a small peg or bolt of metal or wood, not necessarily pointed, employed as a fastening to connect together different parts of an article, as a stop to limit the motion of some moving piece in a machine, as a support on which a small wheel may turn, etc., but most commonly a small metal spike, used for fastening portions of fabrics together, having one end pointed and at the other a bulbed head, or some other arrangement for preventing the spike from passing entirely through the cloth or other material with which it is employed. In one form or another pins of this last kind are of the highest antiquity, the earliest form doubtless being a natural thorn. Pins of bronze, and bronze brooches in which the pin is the essential feature, are of common occurrence among the remains of the bronze age. The ordinary domestic pin had become in the 15th century an article of sufficient importance in England to warrant legislative notice, as in 1483 the importation of pins was prohibited by statute. In 1540 Queen Catherine received pins from France, and again in 1543 an act was passed providing that "no person shall put to sale any pinnes but only such as shall be double headed, and have the heads soldered fast to the shank of the pinnes, well smoothed, the shank well shapen, the points well and round filed, canted and sharpened." At that time pins of good quality were made of brass; but a large proportion of those against which the legislative enactment was directed were made of iron wire blanché and passed as brass pins. To a large extent the supply of pins in England was received from France till about 1626, in which year the manufacture was introduced into Gloucestershire by John Tilsby. In 1636 the pinmakers of London formed a corporation, and the manufacture was subsequently established at Bristol and Birmingham, the latter town ultimately becoming the principal centre of the industry. So early as 1775 the attention of the enterprising colonists in Carolina was drawn to the manufacture by the offer of prizes for the first native-made pins and needles. At a later date several pin-making machines were invented in the United States. During the War of 1812, when the price of pins rose enormously, the manufacture was actually started, but the industry was not fairly successful till about the year 1836 when the Howe Manufacturing company was formed at Birmingham, Connecticut. Previous to this an American, Lemuel W. Wright, had in 1824 secured in England a patent for a machine to make solid-headed pins, which established the industry on its present basis.

Modern Pin Machinery.—In a modern pin-making machine wire of suitable gauge running off a reel is drawn in and straightened by passing between straightening pins or studs set in a table. When a pin length has entered it is caught by lateral jaws, beyond which enough of the end projects to form a pin-head. Against this end a steel punch advances and compresses the metal by a die arrangement into the form of a head. The pin length is immediately cut off and the headed piece drops into a slit sufficient-

ly wide to pass the wire-through but retain the head. The pins are consequently suspended by the head while their projecting extremities are held against a revolving cutter, by which they are pointed.

Then follows the finishing process, which consists of giving the pins the coating of tin which makes them silvery in appearance. In the case of brass pins, they are scoured, cleaned in argol (bitartrate of potash) and water and then tinned in a vat in a solution of water, oxalic acid and granulated tin mixed with the pins at a temperature of 100°C. Iron pins are tinned by an electrolytic process in an alkaline solution of a tin salt. After being washed and dried the pins are polished by being revolved in a barrel, mixed with dry bran or fine sawdust, from which they are winnowed as finished pins. The sizes of ordinary pins range from the $\frac{3}{8}$ -in. stout blanket pin down to the finest slender gilt pin used by entomologists, 4,500 of which weigh about an ounce.

PINACEAE: see GYMNOSPERMES.

PINACOTHECA, the Greek name for a picture gallery, apparently reserved in Greece for one that was public, although used by the Romans for a picture gallery in a private house. In modern usage the term usually means the chamber forming the left wing of the Propylaea of the Athenian acropolis, which was used in ancient times as a picture gallery (Pausanias Bk. II., xxi. 6). Various modern public picture galleries bear the same or a similar name, such as those of Bologna and Turin, and at Munich the old and the new Pinakothek.

PINAR DEL RÍO, capital of Pinar del Río province, Cuba, about 107 mi. S.W. by rail and highway from Havana. Pop. (1949 est.) 64,000. The city, in the fertile Guama valley, is the centre of the tobacco industry of the Vuelta Abajo region. Its port is La Coloma, on the southern coast. The pueblo was created after 1773; but the settlement goes back to 1571 and the oldest parochial church dates from 1710.

PINCHBECK. When brass, the familiar alloy of copper and zinc, contains 12% to 15% of the latter metal, its colour simulates that of gold. In 1732, a London clockmaker, Christopher Pinchbeck, introduced a brass containing about 15% of zinc for the manufacture of imitation gold jewellery, and the yellow metal bore his name; hence the use of the term "pinchbeck" for flash or imitation jewellery. (See BRASS.)

PINCHOT, GIFFORD (1865-1946), American forester and public official, was born at Simsbury, Conn., on Aug. 11, 1865. He graduated at Yale in 1889 and afterwards studied at the École Nationale Forestière, Nancy, France, and for briefer periods in Switzerland, Germany and Austria. Upon his return he began the first systematic forestry work in the United States, in the Vanderbilt forest at Biltmore, N.C. In 1896 he was made a member of the National Forest Commission that worked out the plan of U.S. forest reserves, and in 1897 he became confidential forest agent to the secretary of the Interior, to examine and report upon the reserves. In 1898 he was appointed chief of the division, later the bureau of forestry in the Department of Agriculture, which office he held until 1910. During the period of his administration, the entire forest system and administrative machinery of the bureau was built up, and Pinchot's enthusiasm and publicity work did much for the conservation movement in general. He also served as a member of the committee on public lands, 1903, and the Inland Waterways Commission, 1907. In 1908 he became chairman of the National Conservation Commission, and in 1910 president of the National Conservation Association. He founded the Yale School of Forestry at New Haven, as well as the Yale Summer School of Forestry at Milford, Pa., and in 1903 became professor of forestry at Yale. He was appointed State forester of Pennsylvania in 1920 and began a systematic administration of the forest areas of that State. From 1923 to 1927 and from 1931 to 1935 he was governor of Pennsylvania, and in his first term forced a reorganization of the State Government and the establishment of a budget system. He was also able, in 1923, to settle an important anthracite coal strike by arbitration. He died in New York, N.Y., on Oct. 4, 1946.

Besides many articles in magazines, he wrote *The White Pine* (1896); *The Adirondack Spruce* (1898); *A Primer of Forestry* (1899);

The Fight for Conservation (1909); *The Training of a Forester* (1917); *To the South Seas* (1930); *Just Fishing Talk* (1936).

PINCKNEY, CHARLES (1757-1824), American statesman, was born on Oct. 26, 1757 at Charleston, S.C.; he was the son of Charles Pinckney (1731-84), first president of the first South Carolina provincial congress (1775), and a cousin of Charles Cotesworth Pinckney and Thomas Pinckney. He was studying law at the outbreak of the Revolutionary War, served in the early campaigns in the South, and in 1779 was elected to the South Carolina house of representatives. He was captured by the British at the fall of Charleston (1780), and remained a prisoner until the close of hostilities. In 1787 he was a delegate to the Federal constitutional convention, and on the same day (May 29) on which Edmund Randolph (*q.v.*) presented what is known, as the Virginia plan, Pinckney presented a draft of a constitution which is known as the Pinckney plan. Although the Randolph resolutions were made the basis on which the new constitution was framed, Pinckney's plan seems to have been much drawn upon. Furthermore, Pinckney appears to have made valuable suggestions regarding phrasing and matters of detail. On Aug. 18, he introduced a series of resolutions, and to him should probably be accredited the authorship of the substance of some 32 or more provisions of the constitution. Pinckney was president of the State convention of 1790 that framed a new constitution for South Carolina, was governor of the State 1789-92, a member of the State house of representatives in 1792-1796, and again governor in 1796-98. From 1799 to 1801 he was a member of the United States Senate. He entered public life as a Federalist, but later became the leader in organizing the Democratic-Republican party in his State, and contributed largely to the success of Thomas Jefferson in the presidential election of 1800. By Jefferson's appointment he was American minister to Spain from 1801 to 1805. In general his mission was a distinct failure, his arrogance and indiscretions finally causing the Spanish government to request his recall. He was again governor of South Carolina in 1806-08, and from 1819 to 1821 was a member of the National House of Representatives, in which he opposed the Missouri Compromise in a brilliant speech. He died at Charleston, S.C., on Oct. 29, 1824.

PINCKNEY, CHARLES COTESWORTH (1746-1825), American statesman, was born in Charleston, S.C. on Feb. 25, 1746, the son of Charles Pinckney (d. 1758), a prominent figure in colonial times, by his second wife, the celebrated girl planter, Eliza Lucas. When a child he was sent to England, like his brother Thomas after him, to be educated. Both of them were at Westminster and Oxford and were called to the bar, and for a time they studied in France at the Royal Military college at Caen. Returning to America in 1769, C. C. Pinckney began the practice of law at Charleston. He was a member of the first South Carolina provincial congress in 1775, served as colonel in the South Carolina militia in 1776-77, was chosen president of the South Carolina senate in 1779, took part in the Georgia expedition and the attack on Savannah in the same year, was captured at the fall of Charleston in 1780 and kept in confinement until 1782. He was an influential member of the constitutional convention of 1787, advocating the counting of all slaves as a basis of representation and opposing the abolition of the slave-trade. He opposed as "impracticable" the election of representatives by popular vote, and also opposed the payment of senators, who, he thought, should be men of wealth. Subsequently Pinckney bore a prominent part in securing the ratification of the Federal constitution in the South Carolina convention of 1788. In 1796 he succeeded James Monroe as minister to France. The Directory refused to receive him, and he retired to Holland, but in the next year, Elbridge Gerry and John Marshall having been appointed to act with him, he again repaired to Paris, where he is said to have made the famous reply to a veiled demand for a "loan" (in reality for a gift), "Millions for defence, but not one cent for tribute,"—another version is, "No, not a sixpence." The mission accomplished nothing, and Pinckney and Marshall left France in disgust, Gerry (*q.v.*) remaining. When the correspondence of the commissioners was sent to the United States Congress the letters "X," "Y" and

"Z," were inserted in place of the names of the French agents with whom the commission treated—hence the "X Y Z Correspondence," famous in American history. In 1800 he was the Federalist candidate for vice president, and in 1804 and again in 1808 for president, receiving 14 electoral votes in the former and 47 in the latter year. From 1805 until his death, on Aug. 16, 1825, he was president general of the Society of the Cincinnati.

PINCKNEY, THOMAS (1750-1828), American statesman and diplomat, was born in Charleston, S.C., on Oct. 23, 1750, a younger brother of Charles Cotesworth Pinckney (*q.v.*). Educated in England, he returned to Charleston in 1773, and was admitted to the bar in 1774. During the American Revolution his early training at the French military college at Caen enabled him to render effective service to Gen. Benjamin Lincoln, Count d'Estaing and Gen. Horatio Gates. In the battle of Camden he was badly wounded and captured, remaining a prisoner for more than a year. Subsequently he was governor of South Carolina in 1787-89; presided over the State convention which ratified the Federal constitution in 1788; and was United States minister to Great Britain in 1792-96. During part of this time (1794-95) he was also envoy extraordinary to Spain, and in this capacity negotiated (1795) the important Treaty of San Lorenzo el Real; by that treaty the boundary between the United States and East and West Florida and between the United States and "Louisiana" was settled (Spain relinquishing all claims east of the Mississippi above 31° N. lat.), and the United States secured the freedom of navigation of the Mississippi to its mouth. In 1796 Pinckney was the Federalist candidate for vice president, and in 1797-1801 he was a Federalist representative in Congress. During the War of 1812 he was a major-general. He died in Charleston on Nov. 2, 1828. The Pinckneys, like many other South Carolina revolutionary leaders, were of aristocratic birth and politics, closely connected with England by ties of blood, education and business relations. This renders the more remarkable their attitude in the American Revolution, for which they made great sacrifices.

See C. C. Pinckney, *Life of General Thomas Pinckney* (Boston, 1895).

PIN-CLOVER (*Erodium cicutarium*), an annual herb of the geranium family (Geraniaceae), called also hemlock stork's-bill, red filaree and pin-weed. It is widespread as a weed in the old world, and is extensively naturalized in North America from Nova Scotia to the Pacific coast, being especially abundant from Texas and Colorado westward to California and Washington, where it is highly esteemed as a forage plant. The larger white-stemmed pin-clover, musk clover or filaree (*E. moschatum*), native to Europe and locally naturalized in the United States, has become very abundant in California valleys.

PINDAR (Gr. Πινδαρος, c. 522-443 B.C.), the great lyric poet of ancient Greece, was born at Cynoscephalae, in Boeotia, at the time of the Pythian games (*fr.* 175, Bergk¹, 193)¹, which is taken by Böckh to be 522 B.C. He would thus be some thirty-four years younger than Simonides of Ceos. He was the son of Daiphantus and Cleodice (or Cleidice). The clan of the Aegidae—tracing their line from the hero Aegeus—belonged to the "Cadmean" element of Thebes, *i.e.*, to the elder nobility whose supposed date went back to the days of the founder Cadmus. Pindar stood, that is, within the circle of those families for whom the heroic myths were domestic records. He had a personal link with the memories which everywhere were most cherished by Dorians, no less than with those which appealed to men of "Cadmean" or of Achaeian stock. And the wide ramifications of the Aegidae throughout Hellas rendered it peculiarly fitting that a member of that illustrious clan should celebrate the glories of many cities in verse which was truly Panhellenic.

Life.—Pindar is said to have received lessons in flute-playing from one Scopelinius at Thebes, and afterwards to have studied at Athens under the musicians Apollodorus (or Agathocles) and Lasus of Hermione. In his youth, as the story went, he was defeated in a poetical contest by the Theban Corinna—who, in reference to his profuse employment of Theban mythology, is

¹The references are to the edition of Pindar by C. A. M. Fennell (1893-99), and the fourth edition of Bergk's *Poetae lyrici graeci*.

said to have advised him "to sow with the hand, not with the sack." There is an extant fragment in which Corinna reproves another Theban poetess, Myrtis, "for that she, a woman, contended with Pindar" (*ὄτι βανὰ φοῖσ'* ἔβα Πινδάρου ποτ' ἔρην)—a sentiment which hardly fits the story of Corinna's own victory. The facts that stand out from these meagre traditions are that Pindar was precocious and laborious. Preparatory labour of a somewhat severe and complex kind was, indeed, indispensable for the Greek lyric poet of that age. Lyric composition demanded studies not only in metre but in music, and in the adaptation of both to the intricate movements of the choral dance (*ὀρχηστική*).

Several passages in Pindar's extant odes glance at the long technical development of Greek lyric poetry before his time, and at the various elements of art which the lyricist was required to temper into a harmonious whole (see, e.g., *Ol.* iii. 8, vi. 91, xiii. 18, xiv. 15; *Pyth.* xii. 23, etc.). The earliest ode which can be dated (*Pyth.* x.) belongs to the twentieth year of Pindar's age (502 B.C.); the latest (*Olymp.* v.) to the seventieth (452 B.C.).¹ He visited the court of Hiero at Syracuse; Theron, the despot of Acragas, also entertained him; and his travels perhaps included Cyrene. Tradition notices the special closeness of his relations with Delphi: "He was greatly honoured by all the Greeks, because he was so beloved of Apollo that he even received a share of the offerings; and at the sacrifices the priest would cry aloud that Pindar come in to the feast of the god"². His wife's name was Megacleia (another account says Timoxena, but this may have been a second wife), and he had a son named Daiphantus and two daughters, Eumetis and Protomache. He is said to have died at Argos, at the age of seventy-nine, in 443 B.C.

Piety.—Among the Greeks of his own and later times Pindar was pre-eminently distinguished for his piety towards the gods. He tells us that, "near to the vestibule" of his house (*Pyth.* iii. 78), choruses of maidens used to dance and sing by night in praise of the Mother of the Gods (Cybele) and Pan—deities peculiarly associated with the phrygian music of the flute, in which other members of Pindar's family besides the poet himself are said to have excelled. A statue and shrine of Cybele, which he dedicated at Thebes, were the work of the Theban artists, Aristomedes and Socrates. He also dedicated at Thebes a statue to Hermes Agoraios, and another, by Calamis, to Zeus Ammon. The latter god claimed his especial veneration because Cyrene, one of the homes of his Aegid ancestry, stood "where Zeus Ammon hath his seat," i.e., near the oasis and temple (*Pyth.* iv. 16). The author of one of the Greek lives of Pindar says that, "when Pausanias the king of the Lacedaemonians was burning Thebes, some one wrote on Pindar's house, 'Burn not the house of Pindar the poet'; and thus it alone escaped destruction." This incident, of which the occasion is not further defined, has been regarded as a later invention³.

Better attested, at least, is the similar clemency of Alexander the Great, when he sacked Thebes one hundred and eight years after the traditional date of Pindar's death (335 B.C.). He spared only (1) the Cadmeia, or citadel, of Thebes (thenceforth to be occupied by a Macedonian garrison); (2) the temples and holy places; and (3) Pindar's house. While the inhabitants were sold into slavery, exception was made only of (1) priests and priestesses; (2) persons who had been connected by private *ξενία* with Philip or Alexander, or by public *ξενία* with the Macedonians; (3) Pindar's descendants. It is probable enough, as Dio Chrysostom suggests (ii. 33), that Alexander was partly moved by personal gratitude to a poet who had celebrated his ancestor Alexander I, of Macedon. But he must have been also, or chiefly, influenced by the sacredness which in the eyes of all Hellenes surrounded Pindar's memory, not only as that of a great national poet, but also as that of a man who had stood in a specially close relation to the gods, and, above all, to the Delphian Apollo.

Praise of Athens.—During the second half of Pindar's life, Athens was rising to that supremacy in literature and art which

was to prove more lasting than her political primacy. Pindar did not live to see the Parthenon, or to witness the mature triumphs of Sophocles; but he knew the sculpture of Calamis, and he may have known the masterpieces of Aeschylus. It is interesting to note the feeling of this great Theban poet, who stands midway between Homeric epos and Athenian drama, towards the Athens of which Thebes was so often the bitterest foe, but with which he himself had so large a measure of spiritual kinship. A few words remain from a dithyramb in which he paid a glowing tribute to those "sons of Athens" who "laid the shining foundations of freedom" (*παῖδες Ἀθαναίων ἐβάλοντο φαεινὰν κρηπίδ' ἐλευθερίας*, fr. 55, Bergk⁴, 77), while Athens itself is thus invoked: ὦ τὰι λιπαραὶ καὶ λουστέφανοι καὶ αἰοίδιμοι, Ἑλλάδος ἔρεισμα, κλειτὰ Ἀθῶναι, δαιμόνιον ποτλίετρον (fr. 54, Bergk⁴, 76). Isocrates, writing in 353 B.C., states that the phrase Ἑλλάδος ἔρεισμα, "stay of Hellas," so greatly gratified the Athenians that they conferred on Pindar the high distinction of *προξενία* (i.e., appointed him honorary consul, as it were—for Athens at Thebes), besides presenting him with a sum of money (*Antidosis*, 166).

One of the letters of the pseudo-Aeschines (*Ep.* iv.) gives an improbable turn to the story by saying that the Thebans had fined Pindar for his praise of Athens, and that the Athenians repaid him twice the sum⁴. The notice preserved by Isocrates—less than one hundred years after Pindar's death—is good warrant for the belief that Pindar had received some exceptional honours from Athens. Pausanias saw a statue of Pindar at Athens, near the temple of Ares (i. 8, 4). Besides the fragment just mentioned, several passages in Pindar's extant odes bespeak his love for Athens. Its name is almost always joined by him with some epithet of praise or reverence. In alluding to the great battles of the Persian wars, while he gives the glory of Plataea to the Spartans, he assigns that of Salamis to the Athenians (*Pyth.* i. 76). In celebrating (*Pyth.* vii.) the Pythian victory of the Athenian Megacles, he begins thus: "Fairest of preludes is the renown of Athens for the mighty race of the Alcmaeonidae. What home, or what house, could I call mine by a name that should sound more glorious for Hellas to hear?" (*Cf. also Nem.* v. 49.)

Pindar's versatility as a lyric poet is one of the characteristics remarked by Horace (*Odes*, iv. 2), and is proved by the fragments, though the poems which have come down entire represent only one class of compositions—the *Epinicia*, or odes of victory, commemorating successes in the great games. The lyric types to which the fragments belong, though it cannot be assumed that the list is complete, are at least numerous and varied.

Fragments.—(1) *ῥῆματα*, Hymns to deities—as to Zeus Ammon, to Persephone, to Fortune. The fragmentary *ὑμνος* entitled *Θηβαίους* seems to have celebrated the deities of Thebes. (2) *Παιᾶνες*, *paeanes*, expressing prayer or praise for the help of a protecting god, especially Apollo, Artemis or Zeus. (3) *Διθύραμβοι*, *Dithyrambs*, odes of a lofty and impassioned strain, sung by choruses in honour of Dionysus. (4) *Προσόδια*, *Processional Songs*, choral chants for worshippers approaching a shrine. (5) *Παρθένια*, *Choral Songs for Maidens*.

(6) *Ῥοπήματα*, *Choral Dance-Songs*, adapted to a lively movement, used from an early date in the cult of Apollo, and afterwards in that of other gods, especially Dionysus. To this class belongs one of the finest fragments (84, Bergk⁴, 107), written for the Thebans in connection with propitiatory rites after an eclipse of the sun, probably that of the 30th of April 463 B.C. (7) *Ἐγκώμια*, *Songs of Praise* (for men, while *ὑμνοι* were for gods), to be sung by a festal company. (8) *Σκόλια*, *Festal Songs*. The usual sense of *σκόδιον* is a drinking-song, taken up by one guest after another at a banquet. But Pindar's *σκόλια* were choral and antistrophic. One was to be sung at Corinth by a chorus of the *ἐροδόουλοι* attached to the temple of Aphrodite Ourania, when a certain Xenophon offered sacrifice before going to compete at Olympia. Another brilliant fragment, for Theoxenus of Tenedos, has an erotic character.

(9) *Θρήνοι*, *Dirges*, to be sung with choral dance and the music of the flute, either at the burial of the dead or in commemorative rituals. Some of the most beautiful fragments belong to this class

⁴Compare Jebb, *Attic Orators*, ii. 143.

¹According to others, his latest poem is the eighth Pythian ode, 450 or 446.

²Πινδάρου γένος, in ed. Ald.

³A. Schäfer, *Demosthenes und seine Zeit*, iii. 119.

(106-110, Bergk⁴, 129-133). A number of small fragments, which cannot be certainly classified, are usually given as ἐξ ἀδῆλων εἰδῶν, "of uncertain class."

The Epinicia.—The ἐπινίκια (sc. μέλη), or ἐπινίκιοι (sc. ὕμνοι), "Odes of Victory," form a collection of forty-four odes, traditionally divided into four books, answering to the four great festivals: (1) Ὀλυμπιονίκαι (sc. ὕμνοι): fourteen odes for winners of the wild olive-wreath in the Olympic games, held at Olympia in honour of Zeus once in four years; (2) Πυθιονίκαι: twelve odes for winners of the laurel-wreath in the Pythian games held at Delphi in honour of Apollo, once in four years, the third of each Olympiad; (3) Νεμεονίκαι: eleven odes for winners of the pine-wreath in the Nemean games, held at Nemea, in honour of Zeus, once in two years, the second and fourth of each Olympiad; and (4) Ἰσθμιονίκαι: seven odes for winners of the parsley wreath in the Isthmian games, held at the Isthmus of Corinth, in honour of Poseidon, once in two years, the first and third of each Olympiad. The Greek way of citing an ode is by the nomin. plur. followed by the numeral, e.g., "the ninth Olympian" is Ὀλυμπιονίκαιθ'. The chronological range of the collection (so far as ascertainable) is 502 B.C. (Pyth. x.) to 452 B.C. (Ol. v.).

The general characteristics of the odes may be briefly considered under the following heads: (1) language; (2) treatment of theme; (3) sentiment—religious, moral and political; (4) relation to contemporary art.

Diction.—The diction of Pindar is distinct in character from that of every other Greek poet, being almost everywhere marked by the greatest imaginative boldness. Thus (a) metaphor is used even for the expression of common ideas, or the translation of familiar phrases, as when a cloak is called (Ol. ix. 97) "a warm remedy for winds." (b) Images for the highest excellence are drawn from the farthest limits of travel or navigation, or from the fairest of natural objects; as when the superlative hospitality of a man who kept open house all the year round is described by saying, "far as to Phasis was his voyage in summer days, and in winter to the shores of Nile" (Isthm. ii. 41); or when Olympia, the "crown" or "flower" of festivals, is said to be excellent as water, bright as gold, brilliant as the noonday sun (Ol. i. ad init.). This trait might be called the *Pindaric imagery of the superlative*. (c) Poetical inversion of ordinary phrase is frequent; as, instead of, "he struck fear into the beasts," "he gave the beasts to fear" (Pyth. v. 56). (d) The efforts of the poet's genius are represented under an extraordinary number of similitudes, borrowed from javelin-throwing, chariot-driving, leaping, rowing, sailing, ploughing, building, shooting with the bow, sharpening a knife on a whetstone, mixing wine in a bowl, and many more. (e) Homely images, from common life, are not rare; as from account-keeping, usury, sending merchandise over sea, the σκυτάλη or secret dispatch, etc. And we have such homely proverbs as, "he hath his foot in this shoe," i.e., stands in this case (Ol. vi. 8). (f) The natural order of words in a sentence is often boldly deranged, while, on the other hand, the syntax is seldom difficult. (g) Words not found except in Pindar are numerous, many of these being compounds which (like ἐναρίμβροτος, καταφυλλοροῦν, etc.) suited the dactylic metres in their Pindaric combinations. Horace was right in speaking of Pindar's "nova verba," though they were not confined to the "audaces dithyrambi."

Subjects.—The actual victory which gave occasion for the ode is seldom treated at length or in detail—which, indeed, only exceptional incidents could justify. Pindar's method is to take some heroic myth, or group of myths, connected with the victor's city or family, and, after a brief prelude, to enter on this, returning at the close, as a rule, to the subject of the victor's merit or good fortune, and interspersing the whole with moral comment. Thus the fourth Pythian is for Arcesilaus, king of Cyrene, which was said to have been founded by men of Thera, descendants of one of Jason's comrades. Using this link, Pindar introduces his splendid narrative of the Argonauts. Many odes, again, contain shorter mythical episodes—as the birth of Iamus (Ol. vi.), or the vision of Bellerophon (Ol. xiii.)—which form small pictures of masterly finish and beauty. Particular notice is due to the skill with which Pindar often manages the return from a mythical

digression to his immediate theme. It is bold and swift, yet is not felt as harshly abrupt—justifying his own phrase at one such turn—καὶ τινα οἶμον Ἰσάμι βραχύν (Pyth. iv. 247).

Religious, Moral and Political Sentiment.—a. The religious feeling of Pindar is strongly marked in the odes. "From the gods are all means of human excellence." He will not believe that the gods, when they dined with Tantalus, ate his son Pelops; rather Poseidon carried off the youth to Olympus. That is, his reason for rejecting a scandalous story about the gods is purely religious, as distinct from moral; it shocks his conception of the divine dignity. With regard to oracles, he inculcates precisely such a view as would have been most acceptable to the Delphic priesthood, viz., that the gods do illumine their prophets, but that human wit can foresee nothing which the gods do not choose to reveal. A mystical doctrine of the soul's destiny after death appears in some passages (as Ol. ii. 66 seq.). Pindar was familiar with the idea of metempsychosis (cf. *ibid.* 68), but the attempt to trace Pythagoreanism in some phrases (Pyth. ii. 34, iii. 74) appears unsafe. The belief in a fully conscious existence for the soul in a future state, determined by the character of the earthly life, entered into the teaching of the Eleusinian and other mysteries. Comparing the fragment of the Θρήνος (114, Bergk⁴, 137), we may probably regard the esoteric element in Pindar's theology as due to such a source.

b. The moral sentiment pervading Pindar's odes rests on a constant recognition of the limits imposed by the divine will on human effort, combined with strenuous exhortation that each man should strive to reach the limit allowed in his own case. Native temperament (φύη) is the grand source of all human excellence (ἀρετή), while such excellences as can be acquired by study (διδασκὰ ἀρεταί, Ol. ix. 100) are of relatively small scope—the sentiment, we may remark, of one whose thoughts were habitually conversant with the native qualities of a poet on the one hand and of an athlete on the other. The elements of ὕγιαι δῶρος—"sane happiness," such as has least reason to dread the jealousy of the gods—are substance sufficing for daily wants and good repute (εὐλογία). He who has these should not "seek to be a god." "Wealth set with virtues" (πλοῦτος ἀρεταῖς διδαιδαλμένος), as gold with precious gems, is the most fortunate lot, because it affords the amplest opportunities for honourable activity. Pindar does not rise above the ethical standard of an age which said, "love thy friend and hate thy foe" (cf. Pyth. ii. 83; Isthm. iii. 65). But in one sense he has a moral elevation which is distinctively his own; he is the glowing prophet of generous emulation and of reverent self-control.

c. The political sentiments of the Theban poet are suggested by Pyth. xi. 52; "In politics I find the middle state crowned with more enduring good; therefore praise I not the despot's portion; those virtues move my zeal which serve the folk." If in Pyth. ii. 87, a democracy is described as δῶλος στρατός, "the raging crowd," it is to be noted that the ode is for Hiero of Syracuse, and that the phrase clearly refers to the violence of those democratic revolutions which, in the early part of the 5th century B.C., more than once convulsed Sicilian cities. At Thebes, after the Persian wars, a "constitutional oligarchy" (δολιγαρχία ἰσθνομος, Thuc. iii. 62) had replaced the narrower and less temperate oligarchy of former days (δυναστεία οὐ μετὰ νόμον); and in this we may probably recognize the phase of Greek political life most congenial to Pindar. He speaks of a king's lot as unique in its opportunities (Ol. i. 113); he sketches the character of an ideal king (Pyth. iii. 71); but nothing in his poetry implies liking for the τυραννίς as a form of government. Towards the Greek princes of Sicily and Cyrene his tone is ever one of manly independence; he speaks as a Greek citizen whose lineage places him on a level with the proudest of the Dorian race, and whose office invests him with an almost sacred dignity. In regard to the politics of Hellas at large, Pindar makes us feel the new sense of leisure for quiet pursuits and civilizing arts which came after the Persian wars. He honours "Tranquillity, the friend of cities" (ἄσυχία φίλπολις, Ol. iv. 16). The epic poet sang of wars: Pindar celebrates the "rivalries of peace."

Love of Natural Art.—Pindar's genius was boldly original; at the same time he was an exquisite artist. "Mine be it to invent

new strains, mine the skill to hold my course in the chariot of the Muses; and may courage go with me, and power of ample grasp" (*Ol.* ix. 80). Here we see the exulting sense of inborn strength; in many other places we perceive the feeling of conscious art—as in the phrase *δαιδάλλειν*, so apt for his method of inlaying an ode with mythical subjects, or when he compares the opening of a song to the front of a stately building (*Ol.* vi. 3). Pindar's sympathy with external nature was deeper and keener than is often discernible in the poetry of his age. It appears, for example, in his welcome of the season when "the chamber of the hours is opened, and delicate plants perceive the fragrant spring" (*fr.* 53, Bergk⁴, 75); in the passage where Jason invokes "the rushing strength of waves and winds, and the nights, and the paths of the deep" (*Pyth.* iv. 195); in the lines on the eclipse of the sun (*fr.* 84, Bergk⁴, 107); and in the picture of the eruption, when Etna, "pillar of the sky, nurse of keen snow all the year," sends forth "pure springs of fire unapproachable" (*Pyth.* i. 20). The poet's feeling for colour is often noticeable—as in the beautiful story of the birth of Iamus—when Evadne lays aside her silver pitcher and her girdle of scarlet web; the babe is found, "its delicate body steeped in the golden and deep purple rays of pansies" (*Ol.* vi. 55).

Relation to Art.—The spirit of art, in every form, is represented for Pindar by *χάρις*—"the source of all delights to mortals" (*Ol.* i. 30)—or by the personified Charites (Graces). The Charites were often represented as young maidens, decking themselves with early flowers—the rose, in particular, being sacred to them as well as to Aphrodite. In Pindar's mind, as in the old Greek conception from which the worship of the Charites sprang, the instinct of beautiful art was inseparable from the sense of natural beauty. The period from 500 to 460 B.C., to which most of Pindar's extant odes belonged, marked a stage in the development of Greek sculpture. The schools of Argos, Sicyon and Aegina were effecting a transition from archaic types to the art which was afterwards matured in the age of Pheidias. Olympia forms the central link between Pindar's poetry and Greek sculpture. From about 560 B.C. onwards sculpture had been applied to the commemoration of athletes, chiefly at Olympia.

In a striking passage (*Nem.* v. *ad. init.*) Pindar recognizes sculpture and poetry as sister arts employed in the commemoration of the athlete, and contrasts the merely local effect of the statue with the wide diffusion of the poem. "No sculptor I, to fashion images that shall stand idly on one pedestal for aye; no, go thou forth from Aegina, sweet song of mine, on every freighted ship, on each light bark." Many particular subjects were common to Pindar and contemporary sculpture. Thus (1) the sculptures on the east pediment of the temple at Aegina represented Heracles coming to seek the aid of Telamon against Troy—a theme brilliantly treated by Pindar in the fifth Isthmian; (2) Hiero's victory in the chariot-race was commemorated at Olympia by the joint work of the sculptors Onatas and Calamis; (3) the Gigantomachia, (4) the wedding of Heracles and Hebe, (5) the war of the Centaurs with the Lapithae, and (6) a contest between Heracles and Apollo, are instances of mythical material treated alike by the poet and by sculptors of his day.

Place in Greek Literature.—In the development of Greek lyric poetry two periods are broadly distinguished. During the first, from about 600 to 500 B.C., lyric poetry is local or tribal—as Alcaeus and Sappho write for Lesbians, Alcman and Stesichorus for Dorians. During the second period, which takes its rise in the sense of Hellenic unity created by the Persian wars, the lyric poet addresses all Greece. Pindar and Simonides are the great representatives of this second period, to which Bacchylides, the nephew of Simonides, also belongs. These, with a few minor poets, are classed by German writers as *die universalen Meliker*. The Greeks usually spoke, not of "lyric," but of "melic" poetry (*i.e.*, meant to be sung, and not, like the epic, recited); and "universal melic" is lyric poetry addressed to all Greece. But Pindar is more than the chief extant lyricist. Epic, lyric and dramatic poetry succeeded each other in Greek literature by a natural development. Each of them was the spontaneous utterance of the age which brought it forth.

In Pindar we can see that phase of the Greek mind which

produced Homeric epos passing over into the phase which produced Athenian drama. His spirit is often thoroughly dramatic—witness such scenes as the interview between Jason and Pelias (*Pyth.* iv.), the meeting of Apollo and Chiron (*Pyth.* ix.), the episode of Castor and Polydeuces (*Nem.* x.), the entertainment of Heracles by Telamon (*Isthm.* v.). Epic narrative alone was no longer enough for the men who had known that great trilogy of national life, the Persian invasions; they longed to see the heroes moving and to hear them speaking. The poet of Olympia, accustomed to see beautiful forms in vivid action or vivid art, was well fitted to be the lyric interpreter of the new dramatic impulse. Pindar has more of the Homeric spirit than any Greek lyric poet known to us. On the other side, he has a genuine, if less evident, kinship with Aeschylus and Sophocles. Pindar's work, like Olympia itself, illustrates the spiritual unity of Greek art.

The fact that certain glosses and lacunae are common to all our mss. of Pindar make it probable that these mss. are derived from a common archetype. Now the older scholia on Pindar, which appear to have been compiled mainly from the commentaries of Didymus (*c.* 15 B.C.), sometimes presuppose a purer text than ours. But the compiler of these older scholia lived after Herodian (A.D. 160). The archetype of our mss., then, cannot have been older than the end of the 2nd century. Our mss. fall into two general classes: (1) the older, representing a text which, though often corrupt, is comparatively free from interpolations; (2) the later, which exhibit the traces of a Byzantine recension, in other words, of lawless conjecture, down to the 14th or 15th century. To the first class belong Parisinus 7, breaking off in *Pyth.* v.; Ambrosianus 1, which has only *Ol.* i.-xii.; Medicus 2; and Vaticanus 2—the two last-named being of the highest value. The editio princeps is the Aldine (Venice, 1513). A modern study of Pindar may be almost said to have begun with C. G. Heyne's edition (1773). Hermann did much to advance Pindaric criticism. But August Böckh (1811-21), who was assisted in his commentary by L. Dissen, is justly regarded as the founder of a scientific treatment of the poet. The edition of Theodor Bergk (*Poetae lyrici graeci*, 1878 new ed. by O. Schröder, 1900) is marked by considerable boldness of conjecture, as that of Tycho Mommsen (1864) by a sometimes excessive adherence to mss. A recension by W. Christ has been published in Teubner's series (2nd ed., 1896), also with Prolegomena and commentary (1896); and by O. Schröder (1908). The complete edition of J. W. Donaldson (1841) has many merits; but that of C. A. M. Fennell (1879-83; new ed., 1893-99) is better adapted to the needs of English students. The *Olympia* and *Pythia* have been edited by B. L. Gildersleeve (1885), the *Nemea* and *Isthmia* by J. B. Bury (1890-92); the *Scholia* by E. Abel (1890, unfinished) and A. B. Brachmann (1903). There is a special lexicon by J. Rumpel (1883). The translation into English prose by Ernest Myers (2nd ed., 1883) is excellent; verse translation by T. C. Baring (1875), and of the *Olympian Odes* by Cyril Mayne (1906), also the edition in the *Loeb Classical Library*, with Eng. trans. by J. Sandys (1915). Pindar's metres have been analysed by J. H. Schmidt, *Die Kunstformen der griechischen Poesie* (Leipzig, 1868-72). On Pindar generally, see L. Schmidt, *Pindar's Leben und Dichtung* (1862); F. D. Morice, *Pindar* (1879); A. Croiset, *La Poésie de Pindare* (1880); G. Lübbert, *Pindar's Leben und Dichtungen* (Bonn, 1882); W. Christ, *Geschichte der griechischen Literatur* (1898); F. Dornseiff, *Pindars Stil* (1921). Bibliographical information on the earlier literature will be found in W. Engelmann, *Scriptores graeci* (1881); see also L. Bornemann, in *Jahresbericht über die Fortschritt der klassischen Altertumswissenschaft* (ed. C. Bursian, vol. cxvi., 1904), with special reference to chronological questions and *Pythia*, i, ii, iii. Some considerable fragments of the paeans were discovered in 1906 by B. P. Grenfell and A. S. Hunt, see *Paeans in Oxyrhynchus papyri* (pt. v. 1908), and A. E. Housman, in *Classical Review* (Feb. 1908).

(R. C. J.; X.)

PINDARICS, the name by which was known a class of loose and irregular odes in fashion in England during the close of the 17th and the beginning of the 18th century. The invention is due to Abraham Cowley, who, probably in Paris, and perhaps in 1650, found a text of Pindar and determined to imitate the Greek poetry in English, without having comprehended the system upon which Pindar's prosody was built up. Cowley published, in 1656, 15 *Pindarique Odes*, which became the model on which countless imitators founded their pindarics. The erroneous form of these poems, which were absolutely without discipline of structure, was first exposed by Congreve, exactly half a century later. The laxity of these "pindarics" attracted the poets of the unlyrical close of the 17th century, and they served the purpose not only of Dryden and Pope, but of a score of lesser poets. Although the vogue of these forms hardly survived the age of Anne, something of the vicious tradition of them still remained, and even in the

odes of Wordsworth, Shelley and Coleridge the broken versification of Cowley's pindarics occasionally survives.

PINDARIS, a word of uncertain origin, applied to the irregular horsemen who accompanied the Mahratta armies in India during the 18th century when the Mogul empire was breaking up. Loosely organized under self-chosen leaders, each band was usually attached to one or another of the great Mahratta chieftains. Their special characteristic was that they received no pay, but rather purchased the privilege of plundering on their own account.

The majority of them seem to have been Mohammedans. When the regular forces of the Mahrattas had been broken up in the campaigns conducted by Sir Arthur Wellesley and Lord Lake in 1802-04, the Pindaris made their headquarters in Malwa, under the tacit protection of Sindhia and Holkar. They usually assembled annually in November to set forth over British territory in search of plunder. In one such raid upon the Masulipatam coast they plundered 339 villages, killing or wounding 682 persons, torturing 3,600 and carrying off much valuable property. In 1808-09 they plundered Gujarat, and in 1812 Mirzapur. In 1814 they were reckoned at 25,000 to 30,000 horsemen, half of them well armed. At last the evil became intolerable, and in 1817 the marquess of Hastings obtained the consent of the East India company to the organized campaign known as the Pindari War. The Pindaris were surrounded on all sides by a great army, consisting of 120,000 men and 300 guns, which converged upon them from Bengal, the Deccan and Gujarat under the supreme command of Lord Hastings in person.

Sindhia was overawed and forced to sign the treaty of Gwalior, consenting to aid in the extirpation of the Pindaris, whom he had hitherto protected. The Peshwa at Poona, the Bhonsla raja at Nagpur and the army of the infant Holkar each took up arms, but were separately defeated. The Pindaris themselves offered little opposition. Amir Khan, by far their most powerful leader, accepted the conditions offered to him. His descendant later became Nawab of the state of Tonk in Rajputana. The rest surrendered or were hunted down, the fate of Chitu, one of the most notorious, being to perish in a tiger's den. These military operations were followed by the pacification of Central India under the administration of Sir John Malcolm.

See J. Grant Duff, *History of the Mahrattas* (1826); and Major Ross of Bladensburg, *Marquess of Hastings* (Rulers of India Series) (1893).

PINDEMONTE, IPPOLITO (1753-1828), Italian poet and author, was born in Verona, Nov. 13, 1753, the son of a rich and cultured nobleman. From 1784-88 he lived in a villa outside the city of Verona and the calm, quiet life there inspired him to write one of his best known works, *Poesie campestri* (1788). From 1788-91 he travelled extensively throughout Europe, visiting France, England and Germany. The result of his travels was his novel, *Abaritè* (1792) and a poem, "La Francia" (1789), written in commemoration of the opening of the French Revolution, which he had greeted with enthusiasm. His fervour was somewhat dampened later, however, by the destruction of his villa by French and Austrian troops in 1796 and by the Reign of Terror in France. From 1809-22 he published his translation of Homer's *Odyssey*, the first canto of which appeared in 1809, the rest following at intervals thereafter.

One of his best works was "I Cimiteri," a poem he never finished but one which probably inspired Ugo Foscolo's poem "Sepolcri," which was dedicated to Pindemonte. His novel in verse, *Antonio Foscarini e Teresa Contarini*, is also celebrated. Other works include *Armínio*, a tragedy in verse, *Elogi di Letterati*, a work of biography and literary criticism, and *Prose campestri*, a companion to his earlier *Poesie campestri*. Pindemonte died at Verona, Nov. 18, 1828.

His brother, **GIOVANNI PINDEMONTE** (1751-1812), poet, dramatist and politician, was born in Verona, Dec. 4, 1751. At various times during his life he held high positions with governments of several of the Italian states, but he spent much time in exile in France, sometimes because of his own misconduct, sometimes because of the fall of the government he was serving.

He wrote lyric poetry, which is not highly regarded, and ten

tragedies modelled after Shakespeare. He died in Verona, Jan. 12, 1812.

PINDUS, the ancient name for the mountains which separate Thessaly from Epirus, often used by modern geographers in a somewhat extended sense. The folded Alpine chains are continued down the western coast of the Balkan peninsula, where in the north they form the Dinaric Alps. In the neighbourhood of Scutari (Skadar), however, the direction of the coast-line undergoes a marked change, associated with a change in the trend of the mountain folds.

In the extended sense the name Pindus is applied to the chain of fold-mountains which extends from the Šar Planina, in the latitude of Scutari, southwards to about the latitude of the Gulf of Arta, and thus includes most of the mountains of Albania. As a rule massive limestones are less developed in the Pindus than in the Dinaric region, so that the karstic type of landscape is less frequent and less repellent than in the north, the prevailing types of rocks being often schists, grits and greenish eruptive rocks, especially serpentines.

The range rises to a maximum height of about 8,000 feet, and in places the original forests, mainly of oak and beech, have been preserved.

PINE, JOHN (1690-1756), English engraver. It is not known where he learned his art, although he may have studied under the Frenchman, Bernard Picart. He operated a printshop in London and thus was able to publish books illustrated with his own engravings. His first important publication, which is also one of the finest examples of his work, was a group of engravings of the ceremonies attending George I's revival of the order of the Bath (1730). His other productions include a copy of the Magna Carta; an edition of Horace and a part of one of Virgil; copies of the tapestries celebrating the defeat of the Spanish armada which hung in the house of lords; and several maps of London.

In 1749 his friend William Hogarth depicted him as the friar in his painting "The Gate of Calais," and from that date Pine was known, to his considerable irritation, as Friar, or Father Pine. In 1755 he and a number of other English artists formed a committee to found a royal academy, but he died 12 years before the plans became a reality. From 1743 until his death he was Blue Mantle Pursuivant in the Heralds' college and he lived there during the last years of his life. He died May 4, 1756. His two sons, Robert (q.v.) and Simon, were both painters.

PINE, ROBERT EDGE (1730-1788), English painter, son of John Pine, was born in London. Nothing is known with certainty about his education, but it is more than likely that his father instructed him in his youth. In 1760 his painting "The Surrender of Calais" won for him first prize for historical subjects in the first exhibition held by the Society of Arts, and three years later he received the same award for his "Canute Rebuking His Courtiers on the Seashore." He became widely known as a painter of portraits, particularly those of contemporary theatrical personalities. His likenesses of David Garrick, painted during this period, are regarded as especially fine. In 1782 he exhibited paintings depicting scenes and characters from Shakespeare's plays and probably in the following year, although the date is not certain, went to the United States, taking the exhibition with him and showing it in Philadelphia. His plan had been to paint the portraits of the leaders of the American Revolution, as well as historical scenes of the important events of the war itself, but this plan never materialized although he did make portraits of a number of contemporary statesmen, including Francis Hopkinson, George Washington, Robert Morris, Benjamin Franklin and John Jay. His picture of Washington later appeared as an engraving in Washington Irving's life of the president. Many of Pine's works went to the Columbian museum in Boston and were destroyed when that institution burned. His American paintings are considered to be, on the whole, inferior to those painted in his native country.

Pine died in Philadelphia, Nov. 18, 1788.

PINE, a name given by the ancients to several resinous, cone-bearing trees. Modern botanists restrict the use of the term to

members of the genus *Pinus* (Pinaceae) which differs from other pineaceous genera in featuring slender, needlelike leaves, borne in fascicles of 2 to 8 (rarely solitary), growing from a basal membranous sheath. Each tuft represents an abortive branch which springs from the axil of a partially deciduous, scalelike leaf, the base of which remains closely adherent to the stem. The numerous staminate catkins are arranged in dense spirals about the bases of young shoots of the season; the 2-celled sessile anthers release an abundance of pollen through longitudinal slits; the ovuliferous flowers are composed of several spirally arranged bracts each subtending a scale with two basal ovules. The fruit of the pines, a cone, requires 2 or rarely 3 seasons to mature. It is composed of numerous woody, armed or unarmed scales spirally arranged about a woody central axis, each bearing 2-winged, or rarely wingless seeds. The cones of several species open at maturity to release their seeds, others remain closed for several seasons; still others require the heat of a forest fire to open them in appreciable quantities. In such instances vast amounts of viable seed are accumulated through the years, which, when released, completely reseed burned-over areas.

The pines, which comprise about 90 species, are widely distributed over the north temperate zone, in the southern portions of which they are chiefly confined to the mountains. In Central America a few are found within the tropics. In more northern regions they frequently form extensive forests which are sometimes hardly invaded by other trees. One species is native to Great Britain; about 30 are indigenous to the United States and Canada. Their soft or hard straight-grained, resinous and often durable woods are suitable for many purposes, and some are among the most esteemed of timber trees.

Of the two-needled species, *P. sylvestris*, the Scotch pine of northern Europe, may be regarded as a type. When produced under optimum growing conditions it is one of the finest of the group, and one of the most picturesque of forest trees. Attaining a height of from 70 to 120 ft., it is of conical habit when young, but in maturity acquires a spreading cedar or mushroomlike top, with a straight trunk, two to four feet in diameter at the base, and gnarled, twisted boughs, densely clothed at the extremities with glaucous green foliage, which contrasts strongly with the fiery red-brown bark. The leaves are rather short, curved, and often twisted; the staminate cones fill the air of the forest with their sulphurlike pollen in May or June, and pollinate the purple carpellate cones, which are at first sessile and erect, and then become recurved on a lengthening stalk; fertilization does not occur until the next summer, and the carpellate cones do not reach maturity until the autumn of the following year. They seldom open and scatter their seeds until the third year. *P. sylvestris* is found, in greater or less abundance, from the hills of Finmark and the plains of Bothnia to the mountains of Spain and even the higher forest slopes of Etna, while in longitude its range extends from the shores of the North sea to Kamchatka. Nowhere more abundant than in the Scandinavian peninsula, this tree is the fir (*fur*, *fura*) of the old Norsemen, and still retains the name in Great Britain, though botanically now classed as a pine. It grows vigorously in Lapland on the lower ground, while in south Norway it occurs up to 3,000 ft., though the great forests from which "Norway pine" timber is chiefly derived are on the comparatively lower slopes of the southeastern dales; in the highest situations it dwindles to a mere bush. It furnishes the yellow deal of the Baltic and Norway. In Germany, both on the mountains and the sandy plains, woods of "kiefer" are frequent and widely spread, while vast forests in the U.S.S.R. and Poland are chiefly composed of this species; in many northern habitats it is associated with the spruce and birch. In Asia it abounds in Siberia and on the mountains of the Amur region; in the European Alps it occurs at a height of 5,600 ft., and in the Pyrenees it is found at still higher elevations. In Great Britain natural forests of Scotch pine of any extent are found only in the highlands, chiefly on the declivities of the Grampians. The tree is not indigenous in southern Britain, but when planted in suitable ground multiplies rapidly by the wind-sown seeds; on many of the sandy moors and commons natural pine woods of large extent have been thus

formed. The heartwood of the finer kinds of Scotch pine is of a deep brownish-red colour, abounding in the resin to which its durability is probably due. For all indoor and most outdoor purposes it is as lasting as oak, and for ship planking is perhaps a little inferior; from its lightness and elasticity it is well-adapted for the construction of yachts and other small fast-sailing craft, and is said to be the best of all wood for masts and large spars; its weight varies from 30 to 40 lb. per cu.ft. Great numbers of young pines are annually cut for railway ties (sleepers), mining timber and numerous agricultural applications; large quantities are consumed for wood pavement. The quality of the timber depends greatly on the soil and position in which the trees are grown. The rapidity of growth is still more variable: in Britain

full maturity is attained in from 70 to 120 years, but in Norway the trunk increases much more slowly; H. Schübeler states that a tree felled in the Alten district (about 70° lat.), measuring 2 ft. 10 in. in diameter, showed 400 annual rings.

In the economy of the northern nations of Europe *P. sylvestris* is an important tree. In Scandinavia and the U.S.S.R., houses are chiefly constructed of its timber; and log huts are made of the smaller trunks and lined and roofed with the bark. The inner bark is twisted into ropes, and, in times of scarcity, is kiln-dried, ground up and mixed with meal.

Vast numbers of Scotch pines are raised in nurseries for artificial planting; the seed is sown in the spring, being just covered with earth, and the seedlings transplanted in the second year into rows for further culture, or

taken direct to the seedbed for final planting; sometimes the seed is sown where the trees are intended to grow. A plantation of young Scotch pines requires frequent and careful thinning as the young trees increase in size; but pruning should be avoided as much as possible, except for the removal of deadwood.

In Great Britain *P. sylvestris* is subject to many insect depredations: the pine chafer, *Hylurgus piniperda*, is destructive in some places, the larva of this beetle feeding on the young succulent shoots, especially in young plantations; the fir weevil, *Hyllobius abietis*, eats away the bark, and numerous lepidopterous larvae devour the leaves; the pine sawfly is also injurious in some seasons.

The removal of all dead branches from the trees and from the ground beneath them is recommended, as most of these insects lay their eggs in the decaying parts of the bark and among the dead leaves.

In common with other pines, *P. sylvestris* is subject to the attacks of various fungi. *Trametes radiciperda* attacks the roots and penetrates to the stem, causing rotting of the wood. The disease is difficult to eradicate, as the mycelium of the fungus travels from root to root in the soil. Rotting of the wood at the base of the trunk is also caused by *Agaricus melleus*, which spreads in the soil by means of its long purple-black, cordlike mycelial strands known as *Rhizomorpha*. Much damage is often caused by species of *Peridermium*, which often invade the soft portions of the inner bark to such an extent as to "ring" the stem or branch, or to cause an abnormal formation of turpentine which soaks into the wood and stops the upward passage of water; this causes the parts above the diseased area to perish.

Plantations in England are generally ready for final cutting in from 60 to 70 years, and many are cleared at a much earlier stage of growth, especially when protected from injury by pests. In England the pine is largely employed as a "nurse" for oak trees, its

conical growth when young admirably adapting it for this purpose; its dense foliage renders it valuable as a shelter tree for protecting land from the wind; it stands the sea gales better than most conifers, but will not flourish on the shore like some other species. This pine is planted for ornament in the eastern United States where it has become sparingly naturalized; it has also proved of value in afforesting treeless lands, as in the national forest in western Nebraska.

Large quantities of turpentine are extracted from this pine in Sweden and the U.S.S.R. by removing a strip of bark, terminating below in a deep notch cut in the wood, into which the turpentine runs, and from which it is scooped as it accumulates; but the product is not equal to that of the silver fir and other species.

Tar is prepared from *P. sylvestris*; it is chiefly obtained from the roots.

Closely allied to the Scotch pine, and perhaps to be regarded as a mere alpine form of that species; is the dwarf *P. pumilio*, the "krummholz" or "knieholz" of the Germans—a recumbent bush, generally only a few feet high, but with long zigzag stems that root occasionally at the kneelike bends where they rest upon the ground. The foliage much resembles that of the Scotch pine, but is shorter, denser and more rigid; the cones are smaller but similar in form. Abounding on the higher slopes of the Bavarian and Tirolese Alps, it is a favourite shelter for the chamois; the hunters call it the "latschen," from its recumbent straggling habit.

The red pine, *P. resinosa*, of southeastern Canada and the northern border of the United

States from Minnesota eastward (so-called from the colour of its bark), is a tree sometimes 120 ft. high, with a trunk 3 ft. or more in diameter. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 in. long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch pine although much employed in shipbuilding.

P. pinea is the stone pine of Italy; its spreading rounded canopy of light green foliage, supported on a tall and often branchless trunk, forms a striking feature of the landscape in that country, as well as in some other Mediterranean lands. The beautiful reddish-brown shining cones, roundedly ovate in shape, with pyramidal scale apices, have been prized from the ancient days of Rome for their edible nutlike seeds (pignons), which are still used as an article of food or dessert. They do not ripen until the fourth year, and are kept in the cone until required, as their abundant oil soon turns rancid.

Nearly approaching this is *P. griffithi*, the Bhotan or blue pine, which differs chiefly in its longer cones and drooping glaucous foliage. It is found in Kumaon and Bhutan and on some of the Nepal ranges, but does not grow in the moist climate of the Sikkim Himalayas; it is found at a height of 7,000 to 12,000 ft., and attains large dimensions.

P. cembra is the stone pine of Siberia and central Europe. It abounds on the Alps, the Carpathians and the Siberian ranges, in Switzerland being found at an altitude of 4,000 to 6,000 ft. The seeds are oily like those of *P. pinea*, and are eaten both on the Alps and by the inhabitants of Siberia; a fine oil is expressed from them which is used both for food and in lamps. The growth of *P. cembra* is slow, but the wood is of remarkably even grain, and is employed by the Swiss wood carvers in preference to any other.

Numerous species of pine are planted for ornament, afforestation and timber production.

North American Pines.—The 35 or more species and major varieties of pine native to North America north of Mexico may be grouped in two sections, the *soft pines* and the *hard pines*.

The *soft pines* have soft, close-grained wood, with thin nearly white sapwood; the sheaths of the leaf clusters fall off early (deciduous); the leaves contain a single fibrovascular bundle, and, excepting those of the nut pines, the leaves are in five-leaved clusters. There are 12 species, only one of which, the eastern white pine, is found east of the Great Plains, the others occurring in the Rocky mountain region and on the Pacific coast.

American soft pines are readily divided into four groups whose botanical designations and features are set forth below.

White Pines.—The eastern white pine (*P. strobus*), known also as Weymouth pine, because of its large size and the soft even grain of its white wood, is one of the most valuable of North American timber trees. It once formed extensive forests from Newfoundland to Manitoba and along the northern border of the United States from Maine to Minnesota and also southward in the mountains to Georgia, but it has been so long sought for by the lumbermen that most of the old trees have long since disappeared. On a deep rich soil *P. strobus* sometimes attains a height of 200 ft., and a trunk diameter of 4 to 6 feet. The wood of the white pine is durable for indoor use, especially when protected

States from Minnesota eastward (so-called from the colour of its bark), is a tree sometimes 120 ft. high, with a trunk 3 ft. or more in diameter. The somewhat glaucous leaves form dense tufts at the ends of the branches, and are 4 or 5 in. long; the ovate blunt cones are about half that length. The tree is of quick growth and the wood strong and resinous, but it is less durable than Scotch pine although much employed in shipbuilding.

P. laricio, the Corsican pine, is one of the noblest trees of this group, growing to a height of 100 or even 150 ft., with a straight trunk and branches in regular whorls, forming in large trees a pyramidal head; the slender leaves, of a dark green tint, are from 4 to 7 in. long; the cones, either in pairs or several together, project horizontally, and are of a light brown colour. This pine abounds in Corsica, and is found in more or less abundance in Spain, southern France, Greece and many Mediterranean countries. The tree is of very rapid growth, but produces good timber, much used in southern dockyards, and very durable, though less strong than that of *P. sylvestris*; the heartwood is of a brownish tint. In southern France it has been planted with success on the drift sands of the Bay of Biscay, though it does not bear the full force of the sea blast as well as the pinaster. In England it grows well in sheltered situations and well-drained soils.

The black pine, *P. nigra*, derives its name from the extreme depth of its foliage tints—the sharp, rigid, rather long leaves of a dark green hue giving a sombre aspect to the tree.

P. pinaster, the cluster or pinaster, is an important species from its vigorous growth in the sand drifts of the coast, for the purpose of binding which it has been grown more extensively and successfully than any other tree, especially on the dunes of the Bay of Biscay. Growing to a height of from 40 to 80 ft., the deeply-furrowed trunk occasionally reaches a diameter of 3 ft.

Soft Pines

Group	Leaves	Cones
White pines <i>P. strobus</i> <i>P. monticola</i> <i>P. lambertiana</i>	in clusters of 5, 4" to 6" long	Long stalked, with thin, unarmed scales; seeds long winged
Stone pines <i>P. albicaulis</i> <i>P. flexilis</i> <i>P. ayacahuite</i>	in clusters of 5, about 3½" long	short stalked, with thick, unarmed scales; seeds short winged or wingless
Foxtail pines <i>P. aristata</i> <i>P. balfouriana</i>	in clusters of 5, about 2" long, persistent for many years	short stalked, the scales armed on the back with a small, often deciduous prickly; seeds long winged
Nut pines <i>P. cembroides</i> <i>P. parryana</i> <i>P. monophylla</i> <i>P. edulis</i>	in clusters of 2 to 4, or solitary, about 2" long	short stalked, few scales, the scales greatly thickened, unarmed, short winged or wingless

by paint, its smooth easily-worked grain rendering it a favourite wood for the house carpenter and joiner. The western white pine (*P. monticola*), a mountain species of the northwestern United States and British Columbia, with light brown wood, is extensively cut for lumber, especially in Idaho.

The sugar pine or giant pine (*P. lambertiana*) of California, the largest of known pines, rises to a height of 200 ft. to 220 ft., with a trunk from 6 ft. to 8 ft., or occasionally 12 ft. in diameter. The head is of a pyramidal form, the lower branches drooping like those of a Norway spruce; its foliage is of a light bright green colour. The pendent cones are very large, sometimes 18 in. long and 4 in. in diameter, with large nutlike seeds, which, pounded and baked, are eaten by the Indians. It is lumbered extensively, the wood being highly valued for indoor carpentry.

Stone Pines.—Stone pines are typically timber-line species, and are more important as protectors of valuable watersheds than for the timber they produce. The whitebark pine (*P. albicaulis*), so-called because of its chalky-coloured bark, extends along the mountains of the Pacific slope from British Columbia to the Sierra Nevada of California and eastward through Idaho to Montana and Wyoming. Limber pine (*P. flexilis*) is essentially a Rocky mountain tree. The Mexican white pine (*P. ayacahuite*) is a Mexican tree which attains its northern limits in the southwestern United States.

Foxtail Pines.—This group attains its name from the fact that the leaves persist on the branches for 10 to 15 years or more and simulate the bushy aspect of a fox's tail. Both are small alpine trees. Bristlecone pine (*P. aristata*) is a tree of the southern Rocky mountains, while foxtail pine (*P. balfouriana*) is found on the Coast and Sierra Nevada ranges of California. Needles of the former have superficial resin canals from which resin is exuded upon the surface of the leaf.

Nut Pines.—Some authorities recognize but one species, *P. cembroides* and classify the other forms as varieties of this species. The single-leaf piñon (*P. monophylla*) features one and sometimes two needles in a fascicle. This tree occurs sporadically through northern Mexico, lower California and the southwestern United States. The Parry piñon (*P. parryana*) is the four-needle piñon of southern California and northern Lower California. Nut pine (*P. edulis*), the most widely distributed tree of the group, like the Mexican piñon has needles in clusters of 2 and 3. The seeds of the group are very large and tasty and are sold in the markets as "pine nuts."

The **hard pines** have usually heavy, coarse-grained, mostly dark-coloured wood, with pale often thick sapwood; the sheaths of the leaf clusters are persistent, except in the Chihuahuan pine (*P. leiophylla*), the leaves have two fibrovascular bundles, and are arranged mostly in three-leaved and two-leaved clusters. There are some 24 species about equally divided in number be-

tween the region east of the Great Plains and the region extending from the Rocky mountains to the Pacific coast.

The group of yellow pines with the leaves ordinarily in three-leaved clusters includes several of the most valuable trees of North America. Among these are the longleaf pine (*P. palustris*), the slash pine (*P. caribaea*), the loblolly pine (*P. taeda*), the pitch pine (*P. rigida*) and the pond pine (*P. rigida* var. *serotina*) of the southern states, and the ponderosa or western yellow pine (*P. ponderosa*) and the Arizona pine (*P. ponderosa* var. *arizonica*) of the Pacific states. Other representatives of the three-leaved group are the Monterey pine (*P. radiata*), the knobcone pine (*P. attenuata*), the digger pine (*P. sabiniana*), and the Coulter pine (*P. coulteri*) of California and Oregon, and also the Chihuahuan pine (*P. leiophylla*) of the Mexican border.

The group of hard pines with leaves usually in two-leaved clusters also comprises several important trees. Among these are the red or Norway pine (*P. resinosa*), the gray or jack pine (*P. banksiana*), the spruce pine (*P. glabra*), the shortleaf pine (*P. echinata*), the Virginia pine (*P. virginiana*), the sand pine (*P. clausa*), and the mountain pine (*P. pungens*), of the region east of the Rocky mountains. Here belong also the lodgepole pine (*P. contorta*), found from New Mexico to Alaska. Another representative of the two-leaved group is the bishop pine (*P. muricata*). The rare Torrey pine (*P. torreyana*), confined to the California coast, is a 5-needle pine, a condition rare among yellow pines.

Longleaf pine (*P. palustris*), is the most notable yellow pine of the southern states; it abounds on sandy soils from the Carolinas and Florida westward to Louisiana and Texas. The most marked feature of the tree is its long tufted foliage—the leaves, of a bright green tint, springing from long white sheaths, being often a foot in length. The tall columnar trunk, sometimes 120 ft. high, furnishes one of the most valued pine timbers of the United States; close-grained and resinous, it is very durable and polishes well; it is largely employed in construction work, and large quantities are exported, especially to Great Britain and the West Indies. This tree is the chief lumber-producing pine of the southern United States; it also yields large quantities of tar and turpentine.

The loblolly pine (*P. taeda*), a tall tree with straight trunk and spreading top, covers great tracts of the "pine-barrens" of the southern states, but also frequently spreads over deserted arable lands that have been impoverished by long and bad farming; hence, the woodsmen call it the "old-field" pine, while, from the fragrance of its abundant resin, it is also known as the frankincense pine. It is a fine species 80 to 100 ft. high, having sometimes a girth of 6 or 8 ft. The timber of this pine, though soft and brittle, is much used for lumber and pulpwood, but the forests of it are of no importance to the naval stores industry because of the poor quality of the derived oils and turpentine. The shortleaf (*P. echinata*) and slash pines (*P. caribaea*) are two other very important timber trees in the south. The latter extends over the Florida keys to several islands in the Caribbean.

The ponderosa, western yellow or bull pine (*P. ponderosa*), which grows from 150 to 200 ft. high, with a massive trunk 5 to 8 ft. in diameter, is noted for its soft easily worked wood which is much softer than most other yellow pines; it is the most widely distributed American pine, being found in the mountain forests of western North America from British Columbia to South Dakota (Black hills) and south to Texas and Mexico. It is the chief lumber pine of the Pacific states where it is second in importance only to the Douglas-fir (*q.v.*). The Coulter pine (*P. coulteri*) is remarkable for its enormous cones (sometimes 1 ft. long, 6 in. in diameter, and weighing more than 4 lb.); the scales end in long hooked points curving upwards; the leaves are long, rigid and glaucous in hue. Closely related to this is the digger pine (*P. sabiniana*) of California, the cones of which are 7 to 9 in. long and 5 to 6 in. in diameter, also with hooked scales; the large nutlike seeds are eaten by the Indians; the tree sometimes attains a height of 80 ft. and a trunk diameter of 4 ft. The beautiful Monterey pine (*P. radiata*), found sparingly along the California coast, is distinguished by the brilliant colour of its foliage. The Torrey pine (*P. torreyana*), with leaves 12 in. long, found only

in a narrow strip some 8 mi. in length, along the coast near San Diego, Calif., and on Santa Barbara island, is the least widely distributed of all known pines.

The pitch pine (*P. rigida*), found from the coast of Massachusetts southwestward throughout the Appalachian region, is a tree of from 40 to 50 ft. in height, with rugged trunk, occasionally 3 ft. in diameter; the short dark-green leaves are in thick tufts, contrasting with the pale yellowish, usually clustered cones, the scales of which are furnished with small curved spines. Large quantities of a low grade tar and pitch have been obtained from this species. The tree is one of the few that will flourish in salt marshes.

Pine Lumbering in the United States.—The various native species of pine, several of which form forests of vast extent, constitute the chief source of softwood (coniferous) lumber produced in the United States. According to releases by the United States Forest Service the production of pine lumber in the United States for 1940 was as follows:

Southern yellow	10,162,000,000 bd. ft.
Ponderosa	3,613,000,000 " "
Eastern white	577,000,000 " "
Western white	433,000,000 " "
Sugar	363,000,000 " "
Lodgepole	59,000,000 " "
Total	15,207,000,000 " "

Commercially, the lumber cut from the various kinds of pine is known as *white*, *yellow*, *ponderosa*, *sugar* and *lodgepole* pine, and is classified under these descriptive names in the census of manufactures. White-pine lumber includes that produced from the eastern white or Weymouth pine, the western white pine, the grey or jack pine and the Norway or red pine, the two last named belonging botanically with the yellow pines. Prior to 1900 the eastern white pine was one of the chief lumber-producing trees in America, but the original forests have become so depleted that the tree now contributes only a minor fraction of the lumber marketed as white pine. The lumber from the eastern white, the grey and the red pine is mostly cut in the northern border states from Maine to Minnesota. Western white-pine lumber is practically all produced in Idaho and Washington.

Yellow-pine lumber is cut mainly in the southern states; 70% of the total is produced in 5 states: Mississippi, Louisiana, Alabama, Texas and Georgia, which rank in the order named. The kinds of pine furnishing yellow-pine lumber all belong to the pitch-pine group, and include the longleaf, loblolly, shortleaf, sand, slash, pitch, spruce, pond, mountain and Virginia pine, the longleaf, shortleaf, loblolly and slash pines ranking among the most important.

Ponderosa-pine lumber, practically all cut from *P. ponderosa*, is produced chiefly in Oregon, 32%; California, 25%; Washington, 14% and Idaho, 12%.

Sugar-pine lumber, cut from a single species (*P. lambertiana*) and produced commercially only in California (97.5%) and Oregon (2.5%), commands the highest average price at the mill of any pine lumber cut in the United States. Lodgepole-pine lumber is produced in small quantities in the Rocky mountain states: Wyoming contributing 48%; Colorado, 42%; Montana, 5% and Utah, 4%, of the total footage.

Sargent, *Manual of the Trees of North America* (1905, 2nd ed. 1922); L. H. Bailey, *Manual of Cultivated Plants* (1924); G. B. Sudworth, "Check List of the Forest Trees of the United States," *U.S. Dept. Agric. Misc. Chr. 92* (1927); W. M. Harlow and E. S. Harar, *Textbook of Dendrology* (1937, 1941). (E. S. Hr.; X.)

PINEAPPLE. Cultivated varieties of pineapple belong to the species *Ananas comosus*. This and other species are members of the family Bromeliaceae and, with one exception, are indigenous to tropical and subtropical America. The exception is Spanish moss, which is native to the west coast of Africa. Earliest written records of pineapple are references to it by Columbus, Gonzalo de Oviedo y Valdes and Sir Walter Raleigh, who found pineapple growing in the West Indies where it was used for food and for wine making.

In a remarkably short time after it was first seen by Europeans, the pineapple was carried to many parts of the world. The Portuguese apparently were responsible for much of its early dissemination. They introduced it to St. Helena shortly after they discovered that island in 1502.

Soon after they carried it to various parts of Africa and to Madagascar and by about 1550 to India. Before the end of the 16th century cultivation of the plant had spread over most of the tropical areas of the world, including some of the islands of the South Pacific. Crowns from fruits carried on board ship for food during voyages were probably the propagating material. They can

PINEAPPLE (*ANANAS COMOSUS*)

remain viable, even when detached, for long periods, certainly for as long as these voyages required.

The pineapple plant resembles agave or some yuccas in general appearance. It has from 30 to 40 stiff succulent leaves closely spaced in a rosette on a thick fleshy stem. With commercial varieties, a determinate inflorescence forms about 15 to 20 months after planting on a flower stalk several inches in length. The originally separate lavender flowers, together with their bracts, each attached to a central axis core, become fleshy and fuse to form the pineapple fruit which ripens five to six months after flowering begins.

Fruits of commercial varieties range from three to six pounds in weight. Most varieties are self-incompatible and therefore do not normally produce seed, though they will do so when crossed with certain other varieties.

There are many varieties of pineapple, but those of greatest commercial importance are the Smooth Cayenne in Hawaii, the Queen group in Australia and South Africa and the Red Spanish in Cuba and Puerto Rico.

When pineapple is planted on plantations, an asphalt-impregnated mulch paper is first laid on well-tilled soil in rows, with the edges covered to anchor the strips of paper. Mulch paper is commonly laid on five-foot centres and the pineapple propagating pieces are inserted through the paper into the soil, so spaced as to give a population of 15,000 to 20,000 plants per acre. In many areas the soil is fumigated with DD (a mixture of dichloropropene and dichloropropane) at the time the mulch paper is laid.

Such fumigation is necessary to kill nematodes parasitic on the roots of the pineapple plants.

Pineapple culture, particularly in Hawaii, makes use of many agricultural chemicals. One of the important uses is in controlling weeds in the spaces between strips of mulch paper. Cultivation for weed control has been practically eliminated by the use of chemicals in many areas where pineapple is grown. Chemical insecticides like DDT and Malathion are used to control harmful insects.

Chemical fertilizers are employed and the kind, amount and timing of the application varies immensely with the soil and weather. On some of the plantations in Hawaii need for fertilization is determined by frequent chemical analysis of representative plants

in the field. By this method, even with fluctuating weather and differing soils, proper adjustments of fertilization to the measured needs of the plants permits a condition of balance in plant nutrition favouring the development of fruit of uniformly high quality.

In the 1950s total world production of pineapples for all purposes usually exceeded 1,500,000 tons annually, of which an estimated 55% was produced in the Hawaiian Islands. Other areas of substantial production were Mexico with roughly 10% of the total, Brazil 10%, Republic of the Philippines 8%, Cuba 6% and Formosa 4%. Hawaii also produced approximately 75% of the world's total supply of canned pineapple products, practically all sold in the United States.

Other areas which produce substantial quantities of canned pineapple products for sale in the United States are the Philippines, Cuba and Puerto Rico. Pineapple canned in Australia, Malaya and South Africa is exported principally to Great Britain.

Except in those countries where it is grown, trade in fresh pineapple is limited. Exceptions are the Azores, which produce fresh pineapple for export to the European continent and Great Britain, and Mexico, Cuba and Puerto Rico which export to the United States.

Since highest quality is not developed except when the pineapple fruit is allowed to become fully ripe on the plant, fresh fruit quality is impaired by long shipment.

In addition to its being processed by canning, some pineapple fruit is frozen or concentrated.

(R. L. Cg.)

PINE BEETLE, the name applied to certain bark- and timber-boring beetles (family Scolytidae) that attack pines and other coniferous trees. They are of particular importance in western North America, where each year they damage an estimated 5,000,000,000-6,000,000,000 bd.ft. of timber, worth more than \$15,000,000.

Some of the most important western species are *Dendroctonus ponderosa*, *D. brevicornis*, *D. barberi* and *D. monticolae*. (See COLEOPTERA; ENTOMOLOGY: *Economic Entomology*.)

(R. L. Wl.)

PINE BLUFF, a city of Arkansas, U.S., 45 mi. S.S.E. of Little Rock, on the south bank of the Arkansas river, at an altitude of 215 ft.; county seat of Jefferson county. It is served by the Missouri Pacific and the St. Louis Southwestern railways, and has a municipal airport (Grider field), served by Chicago and Southern Air Lines.

The population in 1950 was 37,162 and in 1940 it was 21,290 by the federal census.

The city stands on bluffs overlooking the river. It is the seat of the state industrial school for boys and of the Arkansas Agricultural, Mechanical and Normal college for Negroes (opened 1875).

Pine Bluff's wholesale and jobbing business covers most of southern Arkansas, parts of Texas, Louisiana and Mississippi. Its industries include railway shops, lumber mills, woodworking plants, factories making locomotives and car castings, brake shoes, cottonseed products and delinting, mixed feeds, archery products, automobile trailers, aluminum foundation ventilators, aluminum garden furniture, electric and welding machinery, electric transformers, oak flooring, pallets, staves, furniture, store fixtures, toys, plywood and cedar boats, millwork, linen supplies, chemicals and ginned cotton.

The city of Pine Bluff is the location of the United States Pine Bluff arsenal.

Pine Bluff was incorporated in 1839.

PINEHURST, a winter resort in the longleaf pine region of the sandhills belt of North Carolina, U.S., 75 mi. S.W. of Raleigh on federal highway 15 and the Norfolk and Southern railroad, 550 ft. above sea level.

The resident population (1950) was 1,016, and the number of visitors averages about 10,000 through the season (from October to May).

Pinehurst was established by James W. Tufts, Boston soda-fountain manufacturer, who purchased 5,000 ac. of cutover timberland from the former ambassador to England, Walter Hines

Page, and his brothers.

Frederick Law Olmsted made the original landscape plan and the town is famous for its winding shrubbery-bordered roads and atmosphere of a small New England country village. It is a leading winter resort for golf, the Pinehurst Country club having three 18-hole courses, all laid out by Donald Ross, the championship course being rated by professionals as one of the best in the country. Except for the national championships, the club's annual North and South golf tournaments are the oldest established amateur and professional events in America. Pinehurst is recognized as providing ideal winter conditions for horses. Aside from the many private riding horses brought down each fall by horse lovers, harness horses, steeplechasers and some runners and show horses are wintered and trained there.

There is an excellent airport near Pinehurst and a modern hospital.

The village is well equipped, there being both a public and a private school, a modern motion-picture theatre, ample store and shopping facilities, a model dairy, a greenhouse, fireproof garage, library, etc.

There is a nonsectarian church for winter visitors known as the Village chapel, a Catholic church and a nonsectarian Community church for the permanent residents.

Many fine winter homes have been built in and around the village and most of these are occupied for the full six months of the season.

Pinehurst is not incorporated as a municipality, the utilities as well as the principal hotels being owned and operated by Pinehurst, Incorporated.

PINEL, PHILIPPE (1745-1826), French physician, was born at St. André, Tarn, Fr., on April 20, 1745, and took his doctor's degree at Toulouse in 1773. He went to Paris in 1778 and for some time supported himself by translating scientific and medical works and by teaching mathematics. In 1798 he published *Nosographie philosophique*, a learned work on the classification of diseases, which gave him much reputation. He decided to devote himself to psychiatry after having been profoundly moved by the case of a friend who went mad, ran into the woods and was devoured by wolves.

He held in succession the posts of chief physician to the famous mental hospitals, the Bicêtre and the Salpêtrière, and it was at the former institution that he took the bold and unprecedented step of removing the chains from the patients, some of whom had been restrained in this way for 30 or 40 years. Pinel, a man of noble character, ranks as the great pioneer in the humane treatment of the insane and as one of the founders of modern psychiatry. He did away with the old violent methods of treatment, such as bleeding, purging and blistering, and advocated simple psychological management.

His *Traité médico-philosophique sur l'aliénation mentale ou la manie* (1801) is one of the great classics of psychiatry. He died in Paris on Oct. 25, 1826.

(W. J. Br.)

PINELLI, BARTOLOMEO (1781-1834), Italian painter and engraver, was born in Rome, where he studied at the Academy of St. Luke. When his father was forced to flee Rome because of debt, Pinelli accompanied him to Bologna and attended school there, returning to Rome several years later. Within a short time after his return Pinelli achieved wide popularity, becoming particularly well known for his scenes of Rome and Tivoli. Pinelli's principal mediums were water colour and etching and his principal subjects, besides landscapes and views, were historical scenes of ancient Greece and Rome, drawings of costumes of the two countries and the illustration of such authors as Virgil, Dante, Tasso, Aretino and Cervantes.

He died at Rome in 1835.

PINENUT or **PINON**: see **NUT**.

PINERO, SIR ARTHUR WING (1855-1934), English dramatist, was born in London on May 24, 1855, the son of John Daniel Pinero, a Jewish solicitor, whose family was of Portuguese origin, long established in London. A. W. Pinero was engaged in 1874 as an actor at the Theatre Royal, Edinburgh, and came to London in 1876, to play at the Globe theatre. Later in the year

he joined the Lyceum company, of which he remained a member for five years. The first piece of his to see the footlights was *£200 a Year*, played in Oct. 1877, at the Globe theatre for the benefit of F. H. Macklin.

The first play to make a hit was *The Money Spinner* (Theatre Royal, Manchester, Nov. 1880); but in *The Squire* (St. James's Theatre, Dec. 1881) he attempted serious drama, and gave promise of the qualities of his later work. In 1883 and 1884 Pinero produced seven pieces, but the most important of his works at this period were the successful farces produced at the Court theatre: *The Magistrate* (March 1885), which ran for more than a year; *The Schoolmistress* (March 1886); *Dandy Dick* (Jan. 1887), revived in February 1900; *The Cabinet Minister* (April 1890), and *The Amazons* (March 1893). Two comedies of sentiment, *Sweet Lavender* (Terry's, March 1888) and *The Weaker Sex* (Theatre Royal, Manchester, Sept. 1888), met with success, and *Sweet Lavender* has enjoyed numerous revivals. With *The Profligate* (Garrick, April 1889) he returned to the serious drama which he had already touched on in *The Squire*. Out of deference to the wishes of John Hare the play was fitted with the conventional "happy ending," but the original denouement was restored, with great advantage to the unity of the play, in the printed version.

The Second Mrs. Tanqueray (St. James's, May 27, 1893) dealt with the converse of the question propounded in *The Profligate*, but with more art and more courage. The piece aroused great discussion, and placed Pinero in the front rank of living English dramatists. It was translated into French, German and Italian, and the part of Paula Tanqueray, created in the first place by Mrs. Patrick Campbell, attracted many actresses, among others Eleonora Duse.

His later plays include *The Notorious Mrs. Ebbsmith* (1895), *The Benefit of the Doubt* (1895), *The Princess and the Butterfly* (1897), *Trelawney of the Wells* (1898), *The Gay Lord Quex* (1899), *Iris* (1901), *Letty* (1903), *A Wife Without a Smile* (1904), *His House in Order* (1906), *The Thunderbolt* (1908), *Mid-Channel* (1909), *Preserving Mr. Panmure* (1911), *The Widow of Wasdale Head* (1912), *Playgoers* (1913), *The Big Drum* (1915), *Mr. Livermore's Dream* (1917), *The Freaks* (1918), *A Seat in the Park* (1922), *The Enchanted Cottage* (1922), *A Private Room* (1928), *Dr. Harmer's Holidays* (1930), *Child Man* (1930) and *A Cold June* (1932). He also wrote (1918) *Monica's Blue Boy*, a play without words, performed to music by Sir Frederic Cowen. He was knighted in 1909. Pinero died Nov. 23, 1934.

His *Plays*, 11 vol. (1891-95), have prefaces by M. C. Salaman. See also H. Hamilton Fyfe, *A. W. Pinero* (1902).

PINEROLO, city and episcopal see of Piedmont, It., in the province of Turin. Pop. (1951) 24,561 (commune). It is built on a hillside just above the valleys of the Chisone and the Lemina, at a height of 1,234 ft. above the sea, 24 mi. by rail S.W. of Turin.

Till 1696 it was strongly fortified with a citadel on Santa Brigida, a castle on S. Maurizio, and city walls constructed by Thomas I of Savoy. It has a cathedral (St. Donatus), the palace of the princes of Acaia and other buildings of some interest. Pinerolo was bestowed on the bishops of Turin by Otto III in 996, but in 1078 the countess Adelaide made it over to the Benedictine abbey of Santa Maria, in whose possession it remained till 1159. Thomas I of Savoy captured the castle in 1188, and in 1246 the commune formally recognized the supremacy of Savoy. Passing in 1295 into the hands of Philip, son of Thomas III, Pinerolo became his residence and capital, a distinction which it retained under Amadeus VIII of Savoy.

Francis I of France obtained possession of the town in his descent into Italy, but Emmanuel Philibert received it back from Henry III in 1574. A second occupation by the French occurred under Cardinal Richelieu. The French language was imposed on the people, great fortifications were constructed, and the fortress (Pignerol) was used as a state prison for such men as Nicolas Fouquet, De Caumont and the "man in the iron mask." Victor Amadeus bombarded the place in 1693, and ultimately compelled Louis XIV to relinquish his hold on it, but before the withdrawal of the French troops the defenses were demolished. In 1748 the town was made a bishop's see.

PING-PONG: see TABLE TENNIS.

PINGUICULA. A genus of carnivorous plants of the family Lentibulariaceae and thus related to *Utricularia* (q.v.) and *Genlisea*. It contains about 30 species, widely distributed in the northern hemisphere and along the Andes to Patagonia in South

America, always in wet situations with acid soil. The plant consists of a rosette of leaves and simple scapes bearing attractive purple or yellow flowers with entire corollas, bilaterally symmetrical and provided with a nectar secreting spur. The trapping mechanism consists of numerous stalked mucilage glands on the upper surfaces of the leaves which are usually ovate in form, with upturned margins. The digestive glands, also numerous, are sessile and depressed to the level of the leaf surface. Only very small flies, etc., can be caught, and experimental attempts to study the digestive powers of the plant by placing larger bits of food (fibrin, etc.) caused decay of the leaf. Larger insects always escape. The glands are of simple structure, much like those of *Byblis*. It was shown by Charles Darwin that the leaves are capable of movement, which, however, is not rapid or of great amplitude. When an insect is caught near the margin, the latter folds over the prey, causing for the time being a greater contact of glands with the body. After some time the margin again unfolds, the process occupying some days, but varying with the temperature. Darwin recorded a cycle of reaction within 24 hr. The response takes place when inanimate objects are placed in suitable positions on the leaf surface. Small leaves, such as those of heaths, and pollen and small seeds were thought by Darwin to be of probable use to the plant, since all contain nitrogen.

The leaves of *Pinguicula* have been used by the Lapps, the Welsh and the peasants of the Italian Alps for the curdling of milk, producing "taettemaelk" (ropy- or long-milk) as it is called in Norway.

See Charles Darwin, *Insectivorous Plants* (New York, 1900); F. E. Lloyd, *The Carnivorous Plants* (Waltham, Mass., 1942).

(F. E. L.; X.)

PINK, in botany, the common name for a numerous genus (*Dianthus*) of the pink family (Caryophyllaceae, q.v.). There are about 250 species, natives of the old world but found chiefly in the Mediterranean region. They are herbaceous perennials of low stature, often with very showy flowers. Four species grow wild in Great Britain: the Deptford pink (*D. armeria*), the maiden pink (*D. deltoides*), the Cheddar pink (*D. caesius*) and the proliferous pink (*D. prolifer*). Two others, the garden pink (*D. plumarius*) and the clove pink or carnation (*D. caryophyllus*), are more or less naturalized in Great Britain. The carnation (q.v.) and picotee are modifications of the clove pink. The sweet-william is derived from the Eurasian *D. barbatus*.

The term pink is also applied to related plants in the genera *Silene* and *Lychnis*, as well as to the sea-pink, or thrift (*Statice armeria*) and the related genus *Limonium*, both members of the family Plumbaginaceae.

PINKERTON, ALLAN (1819-1884), U.S. detective, was born in Glasgow, Scot., Aug. 25, 1819. In 1842 he emigrated to Chicago, Ill., and in 1843 he moved to Dundee, Kane county, Ill. There he ran down a gang of counterfeiters and was then appointed a deputy sheriff of Kane county in 1846 and immediately afterward of Cook county, with headquarters in Chicago. There he organized a force of detectives to capture thieves who were stealing railway property. This organization developed in 1852 into Pinkerton's National Detective agency, since well-known for its activities in industrial disputes, etc. Some of his notable successes were the capture of the principals in the theft of \$700,000 from Adams Express company in 1866, and the uncovering of a plot to assassinate President-elect Lincoln in February 1861, when he arrived in Baltimore on his way to Washington. In 1861 Pinkerton organized a system of obtaining military information in the southern states, and from this system he developed the federal secret service. One of his detectives, James McParlan, from 1873 to 1876 lived among the Molly Maguires (q.v.) in Pennsylvania and secured evidence which led to the breaking up of the organization. Pinkerton died in Chicago on July 1, 1884. He published *The Molly Maguires and the Detectives* (1877); *The Spy of the Rebellion* (1883), in which he gave his version of President-elect Lincoln's journey to Washington; and *Thirty Years a Detective* (1884).

PINKNEY, WILLIAM (1764-1822), U.S. lawyer and statesman, was born in Annapolis, Md., on March 17, 1764. He

was admitted to the bar in 1786, and from 1788 to 1792 practised in Harford county. In 1788 he was a member of the state convention which ratified the federal constitution for Maryland (1788-92), and in 1795 of the house of delegates (where in 1788 and 1789 he defended the right of slave owners to free their slaves), and from 1792 to 1795 of the state executive council. From 1796 to 1804 he was commissioner to England to determine the claims of American merchants under the Jay Treaty of 1794. In May 1806, with James Monroe, then minister at London, he was commissioned to treat with the British government concerning the capture of neutral ships in time of war; from 1807 to 1811, after Monroe's return to America, he was resident minister in London. He was elected to the Maryland senate in Sept. 1811 and later was attorney general of the United States, until 1814. In Aug. 1814 he was wounded at Bladensburg. He served in the federal house of representatives Jan.-April 1816, and from 1816-18 was minister plenipotentiary to Russia and special minister to Naples. He was a member of the committee which drew up the Missouri Compromise. He was a member of the United States senate from 1820 until his death, at Washington, on Feb. 25, 1822.

See William Pinkney (1810-83), *The Life of William Pinkney* (1853); Henry Wheaton, *Some Account of the Life, Writings and Speeches of William Pinkney* (1828).

PINNACLE, in architecture, any vertical, decorative motive serving as the upper termination of a building or other form; hence, metaphorically, a summit or topmost limit. The word is distinguished from finial (*q.v.*) as signifying a larger motive, sometimes of considerable complexity, whereas a finial is a single ornament, and from tower or turret by the fact that a pinnacle is always a strictly subsidiary motive. Thus a Gothic tower and spire may be decorated with pinnacles, each one of which is capped by a finial. The chief architectural development of the pinnacle was in connection with buttresses (*q.v.*) of late Romanesque and Gothic buildings, as the addition of a pinnacle to a buttress not only added to the stability by increasing the weight, but also gave a decorative termination to the vertical line. Earlier pinnacles are simple square or rectangular structures capped with gable roofs or small spires, as in St. Remi at Reims (middle 12th century), and in the west front of Rochester cathedral (1130). With the development of the flying buttress (*q.v.*) pinnacles were increased greatly in size, and, especially in France, in richness, and usually decorated with colonnettes on the outer corners and arches and crocketed gables above, sometimes with the addition of slender crocketed spires. Those of Notre Dame at Paris (end of 12th and beginning of 13th centuries) are typical. The most beautiful of the developed Gothic buttress pinnacles are those of the choir of Reims cathedral (*c.* 1220), in which the solid portion is preceded by an open shrine with a statue of an angel. In England, pinnacles were especially developed during the Decorated period (*q.v.*) and play an important part in the tower designs in which they serve to soften the transition between a square tower and a spire above. Characteristic examples are those of Beverley minster (*c.* 1350) and the tower of St. Mary's at Oxford (*c.* 1300).

PINOCHLE (also spelled pinocle, penuchle, binocle), a card game widely played in the U.S. in several variants. According to one account, it was invented in the 17th century by a Swedish schoolmaster, Gustave Flaker, who called it Flakernuhle. This story is probably folk etymology. Though pinocle is popularly regarded as a European game, there is no evidence that it was played there before the late 1860s, at which time it was flourishing in the U.S. It was probably developed by Germanic immigrants out of *bézique* (*q.v.*), with which its earliest-known form is almost identical. One attempt to account for the name pinocle points out that *bézique* may have been taken to be *besicles* (Fr.,

eyeglasses), and that the new game may have been humorously dubbed *binocle*, another kind of eyeglass. According to R. F. Foster, the *h* was added by a fanciful printer.

The idea of all pinocle games is to *meld* (Ger., announce) certain scoring combinations of cards and to win tricks containing counting cards. A pack of 48 cards is used, containing duplicates in each suit of the ace, ten, king, queen, knave, nine, which rank downward in that order. When won in a trick an ace counts 11; a ten, 10; a king, 4; a queen, 3; a knave, 2; a nine, nothing.

Melds.—The following combinations score the number of points indicated, in any pinocle variant.

Sequence or flush (A, K, Q, J, 10 in trumps)	150
Royal marriage (K, Q in trumps)	40
Marriage (K, Q in any other suit)	20
Four aces, one in each suit ("Hundred aces")	100
Four kings, one in each suit ("Eighty kings")	80
Four queens, one in each suit ("Sixty queens")	60
Four knaves, one in each suit ("Forty jacks")	40
Pinocle (♠ Q and ♦ J)	40
Dix (pronounced "deece"), lowest trump	10

The dix is the 9 of the trump suit except when (rarely) a 64-card pack is used, including two 8s and two 7s of each suit, when the 7 of trumps becomes the dix.

Two-hand Pinocle.—Twelve cards are dealt to each player, three at a time. The next card is turned up and fixes the trump suit. The undealt cards are placed over the trump card so as partly to cover it, and become the "stock." If the trump card is a dix, dealer scores 10.

Nondealer leads first. A card led by one player and the card played to it by the other constitute a trick, and is won by the card led unless the opponent plays a higher card of the same suit, or a trump on a plain-suit lead. Any card may be led, and any card played; until the stock is exhausted it is not necessary to follow suit.

After winning a trick, a player may place face up on the table any meld, and score the points therefor, subject to the following rules: Only one meld may be made in a turn. For each meld, at least one card must be taken from the hand and placed on the table. The same meld may be repeated only with entirely different cards from those used previously. A king or queen melded in a sequence may not thereafter be used in a marriage.

The winner of a trick may also exchange a dix for the trump card, or may merely show the dix, and score 10.

Cards once melded remain on the table but are available for play as though they were in the player's hand.

After the winner of a trick has had a chance to meld, each player draws a card from the top of the stock, the winner drawing first and then leading to the next trick.

When only one card of the stock plus the trump card remains, there can be no more melding. The winner of the next trick turns up the last card of the stock and then takes it into his hand; his opponent takes the trump card. Melds remaining on the table are picked up. The last 12 tricks are played, and each player must, if able, follow suit to the card led; if a trump is led he must win the trick if he can; and if he cannot follow to a plain-suit lead he must play a trump if he has one. The winner of the last trick scores 10. The cards in the tricks are counted and added to the player's score in even 10s, a remainder of less than 7 points not counting.

The game is won by the first player to reach 1,000. A player may call himself out in the middle of the play, and if his score, including his melds and tricks in the current deal, equals 1,000, he wins the game even though his opponent has a higher score; but if he has less than 1,000 he loses the game. If both sides pass 1,000 without calling out, game becomes 1,500 points; and so on.

The game with the 64-card pack is the same except that 16 cards are dealt to each player.

Auction Pinocle.—There are three active players, but it is customary for four to play, the dealer taking no cards. Each player receives 15 cards, dealt in rounds of 4, 4, 4, 3 or 3, 3, 3, 3 at a time; a 3-card "widow" is dealt at the end of the first round of dealing.

The player at dealer's left has the first turn to bid. It is customary to rule that the first bid must be at least 300; in some games the minimum is 250, in others, 200. Each active player in clockwise rotation may bid as long as he overcalls the preceding bid, but if he once passes he may not thereafter enter the bidding. All bids are in units of 10 points.

The bidder (highest bidder) then exposes the three cards of the widow and adds them to his hand. He names the trump suit and places on the table, face up, whatever melds he wishes to show. He then buries (discards) any three other cards face down from his hand; these count as his first trick. He restores the cards melded to his hand and leads a card. No player other than the bidder may meld.

The bidder's two opponents combine in temporary partnership against him. Three cards, one from each hand, constitute a trick, which is won by the highest trump if it contains one, and otherwise by the highest card of the suit led. Of identical cards, the one played first outranks the other. The winner of each trick leads to the next. Each player must follow suit to the card led if he can; when a trump is led he must win the trick if he can. When he cannot follow suit but has a trump, he must play a trump.

The winner of the last trick scores 10. The values of the cards won in tricks are computed, and if the bidder's score for melds plus cards at least equals the amount of his bid, his contract is made. Each opponent (including the dealer) pays him in chips, on the following or a similar schedule:

If the bid was 250 to 290, 1 chip; 300 to 340, 3 chips; 350 to 390, 5 chips; 400 to 440, 10 chips; 450 to 490, 15 or 20 chips; 500 to 540, 20, 30 or 40 chips; the values of these bids depend on the custom of the club or group. If spades are trump, payment is double in each case.

If the bidder concedes defeat without leading to the first trick, he is "bete" (beaten; pronounced "bate") and pays each opponent in accordance with the schedule above. If the bidder led to the first trick and then failed to fulfil his contract, he is "double bete" and pays each opponent double.

In most games there is an imaginary extra player called the "kitty," who participates in payment and collection as an opponent of the bidder. In such games, when the compulsory first bid is passed by the other two active players, the bidder may concede defeat without looking at the widow, in which case he pays only a forfeit of one chip to the kitty.

The principal pinochle rules, established by custom, are: The bidder may change his meld, the trump suit or the cards he buries as often as he wishes before leading to the first trick, but not thereafter. If he buries a card he melded, and leads before correcting it, he loses. Any failure to play according to law forfeits the contract for the side in error. There is no penalty for a bid out of turn, or for an insufficient bid or for a bid by a player who has passed, it is merely void. A player who prematurely exposes a card of the widow must pay the value of the highest bid last made to each other player.

Many players simplify the count of cards by valuing aces and tens 10 each, and kings and queens 5 each; others simplify still further by calling aces, tens and kings 10 each. Other cards have no scoring value. The total of points to be taken in tricks is in every case 240 plus the 10 points for last trick.

Partnership Pinochle.—Four play, two against two as partners, the partners being seated alternately. The dealer gives 12 cards to each player, 3 at a time, but turns up his last card to fix the trump; if this card is a dix the dealer scores 10, and if it is any other card each other player in turn to the left may exchange a dix for it. Each player then shows his meld. Partnerships score jointly, but a player may not combine any card with a card from his partner's hand to form a meld. Once shown, the melds are picked up.

The player at dealer's left leads first. The rules of play are as in auction pinochle. If a side fails to win a trick, it loses its count for melds on that deal. It is usual to penalize a revoke by loss of the offending side's entire count for cards.

The first side to amass 1,000 points wins the game; a player may claim game at any time, or the game may continue to 1,500, as in two-hand pinochle (see above).

In many circles partnership auction pinochle is more popular. No trump card is turned, but each player in turn, beginning at dealer's left, has one bid. The high bidder names the trump. The nonbidding side always scores whatever points it makes; the bidder's side scores all it makes if it at least fulfils its contract, but if it falls short, the amount of its bid is subtracted from its score. Many forms of partnership auction pinochle have been developed, including firehouse pinochle, check pinochle and others.

See A. P. George, *Auction Pinochle* (1913); Albert H. Morehead, *The Modern Hoyle* (Philadelphia, 1949); E. Culbertson, *Card Games Complete*, ed. by A. H. Morehead and G. Mott-Smith (New York, 1952).

PINSK, a town of the Byelorussian S.S.R. (ceded by Poland in 1945), on the Pina river, 196 mi. S.W. by rail of Minsk.

The river Pina connects the town with the fertile regions in the basin of the Dnieper, and, by means of the Dnieper-and-Bug canal, with western Poland and Prussia, while the Oginski canal connects it with the basin of the Niemen. Pottery, leather, oil, soap and beer are the chief products of the local industries. The draining of the marshes around Pinsk was begun by the Russian government in 1872. Pinsk (Pinesk) is first mentioned in 1097 as a town belonging to Sviatopolk, prince of Kiev. In 1132 it formed part of the Minsk principality. After the Mongol invasion of 1239-42 it became the chief town of a separate principality, and continued to be so until the end of the 13th century. In 1320 it was annexed to Lithuania; and in 1569, after the union of Lithuania with Poland, it was the chief town of the province of Brest. Pinsk was annexed to Russia in 1795, and restored to Poland in 1918. Soviet troops occupied it in 1939, and it was taken by Germany in 1941, during the Russian invasion.

PINT, a liquid measure of capacity, equivalent to $\frac{1}{4}$ of a gallon (derived probably through Spanish from Lat. *pincta*, *picta*, a painted or marked vessel). The imperial British pint = .57 of a litre, 34.66 cu.in. The United States standard pint = .47 of a litre, 28 $\frac{1}{2}$ cu.in.

PINTA (MAL DEL PINTO, CARATE) is a cutaneous disease characterized by discoloration of infected areas, with loss of colour or the development of a bluish, violet, reddish, black or even yellowish hue. At one time believed to be caused by a fungus growth, in 1938 pinta was demonstrated to be caused by a spirochaete, *Treponema carateum* (synonym, *T. herrejonii*), a relative of the agents of syphilis and yaws. The disease is highly prevalent in certain states of Mexico, in parts of Cuba and other West Indian islands, and throughout Central America and most of South America. It possibly occurs among the natives of the Marshall Islands and other South Pacific island groups. Transmission is from contact between a weeping open lesion and the abraded or ulcerated skin of an uninfected person. Following an incubation period of 7 to 20 days an initial lesion develops and increases in size. In about five months secondary lesions, at first hyperpigmented, later depigmenting, appear over the body, particularly on exposed skin. A third stage is distinguished by progressive patchy depigmentation and thickening of the affected areas. During the earlier stages the spirochaetes can be recovered from the lesions. Treatment and prophylaxis are similar to those for yaws (*q.v.*).

PINTO, FERNÃO MENDES (1509-1583), Portuguese adventurer, was born at Montemor-o-Velho, of poor parents, and entered the service of a noble lady in Lisbon. He embarked for India in 1537 in a fleet commanded by the son of Vasco da Gama, and for 21 years travelled, fought and traded in China, Tartary, Pegu and the neighbouring countries, sailing in every sea, and introducing the musket into Japan. Though he was 13 times a captive and 17 times sold into slavery, his gay and dauntless spirit brought him through every misfortune. He was soldier and sailor, merchant and doctor, missionary and ambassador; moreover, as the friend and travelling companion of St. Francis Xavier, he lent the apostle of the Indies the money with which to build the first Jesuit establishment in Japan.

In Jan. 1554 Pinto was in Goa, India, waiting for a ship to take him to Portugal, when he decided to devote a large part of his capital to the evangelization of Japan. The viceroy appointed him ambassador to the king of Bungo in order to give the mission an official standing, and on April 18 he set sail with the provincial, Father Belchior Nunes. The missionaries did not reach Japan until July 1556. On Nov. 14, 1556, Father Belchior and Mendes Pinto began their return voyage and reached Goa on Feb. 17, 1557. During his stay of a year there, Pinto left the company, being dispensed from his vows for want of vocation at his own request, though a modern authority states that he was expelled because he was a *marrano*, i.e., had Jewish blood. He finally returned to Portugal on Sept. 22, 1558, and settled at Pragal near Almada, where he married and wrote his famous book, *The Peregrination*; the manuscript, in fulfilment of his wishes, was presented by his daughter to the Casa Pia for penitent women in Lisbon, and it was published by the administrators in 1614. Philip II of Spain gave him (1583) a pension for his services in the Indies. But the reward came too late, for he died on July 8.

Pinto was on the whole a careful observer and truthful narrator, but he invented on occasion, and often repeats stories at second hand. Some witty Portuguese parodied his name into *Fernão, mentes! Minto!* ("Ferdinand, do you lie? I do!") and the English dramatist William Congreve only expressed the general opinion of the unlearned when he wrote in *Love for Love*, "Mendes Pinto was but a type of thee, thou liar of the first magnitude." In the narrative portions of his work Pinto's style is clear and natural.

See Christovão Ayres, *Fernão Mendes Pinto* (Lisbon, 1904), *Fernão Mendes Pinto e o Japão* (Lisbon, 1906); Jordão de Freitas, *Subsídios para a biographia de Fernão Mendes Pinto* (Coimbra, 1905).

PINTURICCHIO (1454-1513), Italian painter of the Umbrian school, whose full name was BERNARDINO DI BETTO (BENEDETTO) DI BIAGIO, the son of a citizen of Perugia, Benedetto or Betto di Biagio. He was probably a pupil of Fiorenzo di Lorenzo; and the two masters appear to have co-operated in the execution of the "Adoration of the Magi" from S. Maria Nuova, now in the Pinacoteca di Perugia. After assisting Perugino in

the execution of his frescoes in the Sistine Chapel, Pinturicchio was employed by Niccolò Buffalini, advocate to the papal consistory, to decorate a little Gothic chapel in Ara Coeli on the Capitol with frescoes illustrating the life of San Bernardino of Siena. These frescoes were probably executed about 1484. They show the master at his best. The colouring is exceedingly harmonious, the landscape backgrounds full of atmosphere. Pinturicchio was employed by the Della Rovere family to decorate a series of chapels in the church of S. Maria del Popolo. The "Adoration of the Shepherds," in the chapel built by Cardinal Domenico della Rovere, was probably done about 1500. In the lunettes under the vault Pinturicchio's assistants painted small scenes from the life of St. Jerome.

The last paintings completed by Pinturicchio in this church were the frescoes on the vault over the retro-choir, a very rich and well-designed piece of decorative work, with main lines arranged to suit their surroundings in a very skilful way. No finer decoration of a quadripartite vault exists.

In 1492 Pinturicchio was summoned to Orvieto, where he painted two Prophets and two of the Doctors in the duomo. In the following year he returned to Rome, and was employed by Pope Alexander VI. (Borgia) to decorate a suite of six rooms in the Vatican, which Alexander had just built. Of these rooms, called after their founder the *Appartamenti Borgia*, five still retain his frescoes. The upper parts of the walls and vaults are not only covered with painting, but further enriched with delicate stucco work in relief. Pinturicchio employed many assistants. The second room, however, with scenes from the lives of saints, was painted by the master himself, and contains one of his famous works, "The Dispute of St. Catherine."

On the vault of the sacristy of S. Cecilia in Trastevere, Pinturicchio painted the Almighty surrounded by the Evangelists. During a visit to Orvieto in 1496 Pinturicchio painted two more figures of the Latin Doctors in the choir of the duomo—now, like the rest of his work at Orvieto, almost destroyed.

Among his panel pictures the following are the most important. An altarpiece for S. Maria de' Fossi at Perugia, painted in 1496–1498, now moved to the picture gallery, is a Madonna enthroned among saints, graceful and sweet in expression. Another fine altarpiece, similar in delicacy of detail, and probably painted about the same time, is that in the cathedral of San Severino—the Madonna enthroned looks down towards the kneeling donor. The Vatican picture gallery has the largest of Pinturicchio's panels—the Coronation of the Virgin, with the apostles and other saints below. Several well-executed portraits occur among the kneeling saints. Other panel paintings by Pinturicchio exist in the cathedral of Spello, in the Siena gallery, at Perugia, and in the collection of the Earl of Crawford at Haigh Hall.

In 1501 Pinturicchio painted several fine frescoes in S. Maria Maggiore at Spello—all very decorative and full of elaborate architectural accessories. One of them, the Annunciation, is signed "Bernardinvs Pinturichivs Pervsivns." The most striking of all Pinturicchio's frescoes, both for brilliance of colour and their wonderful state of preservation, are those in the cathedral library at Siena, a large room built in 1492 by Cardinal Francesco Piccolomini, afterwards Pius III. In 1502 the cardinal contracted with Pinturicchio to decorate the whole room with arabesques on the vault, and on the walls ten scenes from the life of Aeneas Sylvius Piccolomini, Pius II., the uncle of Cardinal Francesco.

The contract specially provided that the cartoons, their transference on to the walls, and all the heads, were to be by Pinturicchio's own hand, thus contradicting Vasari's assertion that the cartoons were the work of Raphael. The series were finished in 1507. Outside the library, over the door, we have the coronation of Pius III. in which he has introduced his own portrait, and standing by him is a youth who bears some resemblance to Raphael. In 1513, the year of his death, he painted a highly finished panel with Christ bearing His Cross, now in the Palazzo Borromeo in Milan. He died at Siena, on Dec. 11, 1513, and is ranked as one of the greater Umbrian painters. His work has been undervalued, partly owing to the dislike which tinges Vasari's biography of him. Even Crowe and Cavalcaselle hardly did him

justice. G. Morelli has however disproved the myth that Raphael, then a youth of 20, supplied cartoons or drawings for the aged master in his work in the Libreria del Duomo, Siena. These drawings (Venice) are not by Raphael but by Pinturicchio.

See G. Morelli, *Italian Masters in German Galleries* (1883); Vermiglioli, *Mémoire de Pinturicchio* (Perugia, 1837); and the valuable notes and appendix of Milanesi's edition of Vasari, iii. 493–531 (Florence, 1878); E. Steinmann, *Pinturicchio* (Leipzig, 1898); E. M. Phillips, *Pinturicchio* (1901); W. Bombe, *Geschichte der Peruginer Malerei* (1912).

PINWELL, GEORGE JOHN (1842–1875), British water-colour painter, was born at Wycombe, and educated at Heatherley's Academy. Like Frederick Walker and A. B. Houghton, he belonged to a group whose style was derived from drawing upon wood for book illustration. As he died young his works are few, but their promise was great. His earliest drawings appeared in *Lilliput Levée*. He did a little work for *Fun* and executed several designs for the silversmiths, Elkingtons. In 1863 his first drawing appeared in *Once a Week*, and from that time his work was in constant demand in current periodicals. His most important productions, made for the Dalziel brothers, were illustrations of Goldsmith, of Jean Ingelow's poems, Robert Buchanan's *Balads of the Affections*, and the *Arabian Nights*. Of Pinwell's pictures in colour, which are distinguished by a remarkable, jewel-like quality and marked by his strong love of pure, bright colour and opalescent effect, the chief are the two scenes from the *Pied Piper of Hamelin*, *Gilbert à Becket's Troth*, *Out of Tune or The Old Cross*, *A Seat in St. James's Park*, and *The Elixir of Life*.

In 1874 Pinwell fell seriously ill and went to Africa for the winter. He painted several remarkable pictures at Tangier, but he returned to die on Sept. 8, 1875.

See G. C. Williamson, *Life of George J. Pinwell* (1900).

(G. C. W.; X.)

PINZON, a family of Spanish navigators, of Palos in Andalusia, three members of which—Martin Alonso, Francisco and Vicente Yañez, brothers—were associated with Columbus in the discovery of America.

MARTIN ALONZO PINZON, born about the middle of the 15th century, in the expedition of 1492, commanded the "Pinta," on which his brother Francisco was pilot. On Oct. 6, he suggested to Columbus (when already in the longitude of the Bermudas) to change the course of the expedition from due west to south-west; on Oct. 7 this suggestion was adopted, bringing the fleet to the landfall at Guanahani (San Salvador, Watling Island) in the Bahamas (Oct. 12, 1492). On Nov. 21, near the east end of the north coast of Cuba, he left Columbus, making eastward in search of the supposed gold-land. On Jan. 6, 1493, he rejoined the admiral, but on the return journey again left him and landed at Bayona in Galicia. He died soon afterwards.

VICENTE YAÑEZ PINZON commanded the "Nina" in 1492–1493 and remained loyal to Columbus throughout. In after years he made important discoveries on his own account. In December 1499 he sailed with four caravels across the Atlantic to the south-west, and on Feb. 7, 1500, he landed at Cape S. Agostinho, near its most easterly projection (called by him Cape Santa Maria de la Consolacion). Proceeding southwards a short distance, he then turned north, followed the coast to the north-west, discovered the Amazon estuary, and went as far as what is now Costa Rica. After touching at Haiti, and losing two of his vessels among the Bahamas, Vicente returned to Palos in September 1500. Although he was created governor of the newly discovered lands by Ferdinand and Isabella, he did not take possession. In 1507 he sailed with Juan Diaz de Solis along the east coast of Central America. In 1509, again with De Solis, he coasted the Atlantic side of South America as far as the La Plata estuary, hoping to find an opening westwards leading to the Spice Islands. According to Herrera, he reached 40° S., not recognizing the La Plata and turning back about the mouth of the Rio Negro, but this is probably an exaggeration. After 1523 all traces of Vicente are lost.

Peschel, *Geschichte der Erdkunde*, pp. 230, 233, 249 (Munich, 1865); *Zeitalter der Entdeckungen*, pp. 305, etc., 426; Jose Maria Asensio, *Cristoval Colon, su vida, sus viajes, sus descubrimientos* (Barcelona, 1891); Cesareo Fernandez Duro, *Colon e Pinzon*.

PIOMBINO, a seaport of Tuscany, Italy, in the province of Livorno, 8 mi. by rail W.S.W. of Campiglia Marittima (which is 53 mi. S.S.E. of Pisa), 62 ft. above sea-level, at the southern extremity of the peninsula of the Monte Massoncello. Pop. (1936) 19,966 (town); 27,672 (commune). It is the port of embarkation for Elba, the nearest point of which is about 6 mi. to the southwest, and originally belonged to Pisa. It gives the title of prince to the Buoncompagni Ludovisi family, who, however, no longer own it. Large iron-smelting and tin plate works are situated here. In 1938 5,812 ships, of 1,455,000 tons, entered and cleared the port. Of this number, 5,794 ships of 1,393,000 tons were Italian.

PIOTRKÓW, a town of Poland, in the province of Lodz, 90 mi. southwest of Warsaw and 5 mi. west of the river Pilica. Pop. (1938) 51,300. It is a well-kept town, with numerous gardens, and has flour-mills, saw-mills, tanneries, agricultural machinery works, and breweries. One of the oldest towns in Poland, Piotrków was in the 15th and 16th centuries the place of meeting of the diets, and here the kings were elected. The town was captured by German troops in 1939, at the outset of World War II.

PIOZZI, HESTER LYNCH (1741-1821), English writer, well known as the friend (Mrs. Thrale) of Samuel Johnson, was born on Jan. 16, 1741, her father being John Salusbury of Bobbel, Carnarvonshire. In 1763 she married Henry Thrale, a rich Southwark brewer, whose house was at Streatham on the south-east corner of Tooting Bec Common. There was very little sympathy between the lively girl and Thrale, who was 13 years her senior, but gradually she drew round her a distinguished circle of friends.

She was introduced to Samuel Johnson in 1765 by Arthur Murphy, who was an old friend of her husband's. In 1766 Johnson paid a long visit to Streatham, and from that time was more or less domesticated with the Thrales. (See JOHNSON, SAMUEL.) Fanny Burney was another of her friends. She was very sensitive, and sometimes thought that Mrs. Thrale gave herself airs of patronage. Meanwhile, in 1772, Thrale was threatened with bankruptcy. The situation was saved by his wife's efforts, and in the next year Thrale travelled, leaving her in charge of his affairs. He was twice returned for the borough of Southwark, chiefly through her efforts. In 1781 Thrale died, and Dr. Johnson helped the widow with her business arrangements, advising her to keep on the brewery, until she "cured his honest heart of its incipient passion for trade, by letting him into some, and only some, of its mysteries." The brewery was finally sold for £135,000.

Mrs. Thrale had met Gabriele Piozzi, an Italian musician, in 1780. In 1784 they were married. Johnson told Miss Burney that he drove the memory of Mrs. Thrale from his mind, burning every letter of hers on which he could lay his hand. The Piozzis presently left England to travel in Italy. At Florence they fell in with Robert Merry and the other "Della Cruscan" writers ridiculed by William Gifford in his *Maeviad* and *Baviad*, and she contributed some verses to their *Florence Miscellany* in 1785. In 1786 she published *Anecdotes of the late Samuel Johnson, during the last twenty years of his life*, which was severely criticized by Boswell. She was ridiculed by "Peter Pindar" in *Bozzy and Piozzi; or the British Biographers, A Town Eclogue* (1786). But though Miss Burney and some others held aloof, the Piozzis found plenty of friends when they returned to London in 1787. Piozzi died at Brynbell, a villa he had built on his wife's Flintshire estate in 1809, and Mrs. Piozzi gave up her Welsh property to her adopted son, and spent most of the rest of her life at Bath and Clifton. She retained her vivacity to the last, celebrating her 80th birthday by a ball to six or seven hundred people at Bath. She died at Clifton on May 2, 1821.

From 1776 to 1809 she kept a note-book which she called "Thraliana." Her well-known poem of the "Three Warnings" is to be found in many popular collections. *Letters to and from the late Samuel Johnson* appeared in 1788; *Observations and Reflections made in the course of a Journey through France, Italy and Germany*, in 1789; and in 1801 she published *Retrospection; or a review of the most*

striking and important events, characters, and situations . . . which the last eighteen hundred years have presented to the view of mankind (1801). See *Letters and Literary Remains of Mrs. Piozzi (Thrale)*, edited with notes and an Introductory Account of her Life and Writings by A. Hayward (1861); *Piozziana; or Recollections of the late Mrs. Piozzi by a Friend* (1833), the anonymous friend being Edward Mangin (1772-1852); L. B. Seeley, *Mrs. Thrale, afterwards Mrs. Piozzi* . . . (1891), and G. Birkbeck Hill, *Johnsonian Miscellanies* (1897); also Percival Merritt, *The True Story of the So-called Love Letters of Mrs. Piozzi* (1928), which exposes the misrepresentation of the "love letters" to William Conway the actor written when she was an old lady and published in 1843. Copies of these letters are shown to be misleading. See also JOHNSON, SAMUEL.

PIPE, a hollow stem of clay, wood or other material with a bowl at one end used for smoking tobacco, opium or other narcotic, or any medicinal substance. See PIPE SMOKING and TOBACCO PIPE.

PIPE and TABOR, a popular mediaeval combination of a small pipe or flageolet and a small drum. The tabor being fastened to the performer's left elbow, the hands remained free, the right beating the little drum with a stick to mark the rhythm, while the left held and fingered the pipe with thumb and first two fingers. The pipe and tabor are said to be of Provençal origin.

PIPE CLAY. A natural clay, one of the names given to impure kaolin or china clay. It occurs in beds where kaolin has been washed away from its original site and deposited in a hollow. It is used to make primitive tobacco pipes and for whitening military belts, etc.

PIPE-FISH, the name given to fishes which, with the sea-horses, form the family Syngnathidae of the order Solenichthyes. Pipe-fishes are long and slender, varying from 1-2 in. to 18 in., usually about 6 in. long when full grown, with the body encased in bony rings, and a small, toothless mouth at the end of a long, tube-like snout; the gill-filaments are reduced in number and appear as rounded lobes or tufts. About 100 species are known from warm seas and a few from rivers. Pipe-fishes frequent seaweeds and swim slowly by rapid undulations of the small dorsal fin.

PIPE-LINE: see PETROLEUM.

PIPER, CARL, COUNT (1647-1716), Swedish statesman, was born at Stockholm on July 29, 1647. In 1689 he was made one of the secretaries of state, and Charles XI recommended him on his deathbed to his son and successor, Charles XII. Piper became the most confidential of the new sovereign's ministers. In 1697 he was made a senator and set over domestic affairs while still retaining his state-secretaryship. In 1698 he was created a count, in 1702 appointed chancellor of Uppsala university and during the first half of the Great Northern War, as the chief of Charles's perambulating chancellery, he was practically prime minister. But he belonged to the school of Bengt Oxenstjerna (*q.v.*) and was therefore an avowed advocate of a pacific policy. He protested in vain against nearly all the military ventures of Charles XII, *e.g.*, the War of Deposition against Augustus of Saxony and Poland, the invasion of Saxony, the raid into the Ukraine. Again and again he insisted that the pacific overtures of Peter the Great should at least be fairly considered, but his master was always immovable. Piper was taken prisoner at Poltava (1709) and died at Schlüsselburg on May 29, 1716.

See W. L. Svedelius, *Count Carl Piper* (1869).

(R. N. B.)

PIPERACEAE, the pepper family, a large group of tropical herbs, vines and small shrubs with simple leaves having a characteristic pungent taste, the numerous small flowers, lacking both calyx and corolla, crowded in dense spikes. Most of the species belong in two genera, *Piper* with more than 2,000 described species and *Peperomia* with more than 1,200. Six other small genera are usually recognized. The family is of considerable economic importance, yielding as it does pepper (*q.v.*), the product of several species; black and white pepper, derived from the fruits of *Piper nigrum*; long pepper, the product of *Piper officinarum* and *P. longum*, and Ashanti pepper, the product of *P. chusii*. Cubebs (*q.v.*) is the fruit of *Piper cubeba*. The leaves of *Piper betle* are widely used in the orient for chewing with slices of betel nut (*Areca catechu*) and lime, while kava (*q.v.*) is a stimulating drink widely used in Polynesia prepared from the roots of *Piper latifolium* (*P. methysticum*).

(E. D. ML.)

PIPERAZINE, a colourless crystalline solid melting at 104° C. and boiling at 145° C., soluble in water and used medicinally as a uric acid eliminant. Chemically, it is hexahydropyrazine (see PYRAZINE) and has the structure

Piperazine, $\text{C}_4\text{H}_{10}\text{N}_2$, was first obtained by A. von Hofmann by the action of ammonia on ethylene dichloride or dibromide. It has been manufactured from the latter dihalide and aniline, the intermediate product, diphenylpiperazine, being converted successively into its dinitroso compound and piperazine. A more recent method of manufacture consists in the elimination of ammonia from ethylene diamine at a temperature of 200° – 300° C. over a metallic catalyst. It is a strongly basic substance and forms salts with acids. The salt with uric acid is soluble in water, hence its use in the treatment of gout.

PIPERINE, an alkaloid (see ALKALOIDS) found in the fruits of certain peppers. It forms white prisms, melts at 128° – 129° C., is almost insoluble in water, but readily so in alcohol or ether, and is a very weak base, salts being only formed with mineral acids, and these are dissociated by water. Alcoholic potassium hydroxide decomposes piperine, $\text{C}_{17}\text{H}_{19}\text{O}_3\text{N}$, into piperidine, $\text{C}_5\text{H}_{11}\text{N}$, and piperic acid, $\text{C}_{12}\text{H}_{19}\text{O}_4$, indicating that the alkaloid is a piperidide of piperic acid. It was synthesized (Rügheimer, 1882) by the action of piperyl chloride on piperidine.

PIPERITONE is the sole ketonic constituent of eucalyptus oils, from which it may be either fractionally distilled or extracted with sodium bisulphite. It occurs in the peppermint group of eucalyptus leaf oils, in association with l - α -phellandrene, and has been found altogether in 23 species; these grow mainly in south-eastern Australia and Tasmania and are characterized by a butterfly-wing leaf venation. A maximum content of about 45% of piperitone is reached in the oil of the broad-leaved peppermint (*E. dives*). Piperitone, $\text{C}_{10}\text{H}_{16}\text{O}$, Δ^1 -menthen-3-one, is a colourless liquid (b.p. 232° C.), with an odour of peppermint. The eucalyptus ketone is laevorotatory, with $[\alpha]_D -51.5^{\circ}$; but a dextrorotatory piperitone, having $[\alpha]_D +49.1^{\circ}$, has been isolated from the essential oil of a Himalayan grass, *Andropogon Iwarancusa*. The optically active ketone racemizes easily, because of enolization. When hydrogenated according to Paal's method, l -piperitone yields mainly d -isomenthone, and by reduction in other ways it has been used commercially as a source of dl -menthol. It may be oxidized to thymol.

PIPERNO (anc. *Privernum*), now called Priverno, a town of the province of Latina, Italy, 54 mi. S.E. of Rome by rail. Pop. (1951), 9,154. The mediaeval town was founded in the 10th century on a hill 490 ft. above sea level, by refugees from the Roman town of Privernum, lower down (118 ft. above sea level) on the highroad, $1\frac{1}{4}$ mi. to the north, at the mouth of a low pass leading through the Volscian mountains to the valley of the Sacco. There are scanty remains of the Roman period, though the ruins are largely mediaeval. The ancient Volscian town probably stood on the site occupied by the mediaeval and modern town. Privernum was captured in 329 B.C., and in 318 the tribus Oufentina was founded (see LATIUM). The mediaeval town has a picturesque piazza, with a Gothic cathedral (1283), and a Gothic town hall; and Gothic churches. Polygonal terrace walls of the Roman or pre-Roman period exist in the vicinity.

See H. H. Armstrong, 44 seq., 170 seq., 386 seq. in *American Journal of Archaeology* (1911).

PIPE ROLLS or the Great Rolls of the exchequer are a long series of financial records of the English crown. The first extant Pipe Roll is that for the 31st year of the reign of Henry I. The continuous series begins with the second year of Henry II's reign and the annual succession of rolls is almost unbroken till 1834, when the last relics of the ancient financial system of the English mediaeval kings were swept away. The most plausible explanation of the name Pipe Rolls is that when rolled up and stacked in their presses the rolls looked like pipes. Up to the be-

ginning of the 13th century the Pipe Rolls are the only consecutive series of official records which have survived; it was not until the reign of John that the Chancery records were systematically preserved. Therefore, the value of the Pipe Rolls for the last half of the 12th century can hardly be overestimated. By them the narratives of the chroniclers can be checked, and from them most of our knowledge of the actual working of the legal system in Henry II's reign comes. They are a mine of information about the personnel of the government and the gradual development of the new administrative offices. They are the best authority for the descents of the great families of feudal England. For the historian of English towns they provide a vast mass of material. Calculations as to the amount of the royal revenue have been made from them, but such calculations can only be approximate, since much money was paid directly into the king's privy purse and recorded in no roll that survives.

Consisting of a varying number of skins of parchment about 14 in. wide and a yard long sewn together at the top, the rolls are not easy to consult. Their matter, too, is not easy reading, nor their method of bookkeeping easy to understand. The accounts are entered county by county, the sheriff being responsible for the account of his shire. Other accounts, known as foreign accounts, appear sometimes on the rolls, accounts of royal manors by their custodians, accounts of escheats, or of towns. The clerks enter debts long after all hope that they may be paid has passed away. The Pipe Roll society, founded in 1883 to print the early Pipe Rolls, had by the middle of the 20th century published the Rolls up to and including that for 1210. In later centuries, the Pipe Rolls lost much of their importance, but interesting matter can be found in the foreign accounts which continue to appear on the rolls. When the escheat rolls begin one great source of foreign accounts is lost to the Pipe Rolls. In this way by a process of splitting off and with the setting-up of new accounting offices the ancient sheriff's account recorded in the Pipe Rolls becomes insignificant and stereotyped. The continuation of the series to 1834 is a remarkable illustration of English administrative conservatism.

(D. M. S.)

PIPE SMOKING. The original source of the idea of smoking must be sought in the sense of smell. This was much keener in primitive man than in man of the more advanced stages. With the pleasure derived from aroma, there was probably a sense of mystery at the sight of the smoke rising up into the air. Thus there was an element of religious ceremony in the burning of pleasant-smelling substances among primitive folk, in whatever part of the world we may be able to study their ways.

The ritual element is enhanced by another circumstance. Herodotus, in the 5th century B.C., described a practice of the Scythians, Mongol people settled in southeastern Europe, between the Carpathian mountains and the Don river. Throwing the leaves of a certain plant (which was probably hemp) upon a fire, they sit around and, inhaling the smoke, "they grow drunk with the fumes as the Greeks do with wine," until they jump up and begin to dance and sing. Herodotus seemed to regard this simply as an orgy; but inhalation was certainly used to produce a super-

FRENCH-CARVED MEERSCHAUM PIPE WITH AMBER MOUTHPIECE

normal condition of mind in many parts of the world. When Columbus discovered America, he found the habit established of inhaling tobacco, to induce trance, during which visions were seen, which were accepted as divine revelations. The intoxicating vapour at Delphi which inspired the Pythian priestess may have been artificially produced, since no natural source has been found.

The invention of an implement to concentrate the smoke was an advance. Such an implement is the Y-shaped tube described by G. Fernandez de Oviedo in his *History of the Indies* (1535). The two horns of the "Y" were inserted in the nostrils, and smoke from tobacco burning in a censer was drawn up through the tube.

SOME CLASSICAL AND CONTEMPORARY PIPES

(1) Modern briar pipes. (2) Burmese pipe made from bamboo root, with decorative fittings. (3) Pipe carved in slate by Indians of northwestern America. The bowl is sunk in the middle of the top. (4) "Tyrolean" style pipe, manufactured in Bavaria, Ger. The mouthpiece and upper part of the stem are of bone, the lower stem is cherrywood and the bowl is briar. (5) Elaborate Persian pipe with a clay bowl and a bone stem finished in gilt and colour decoration. (6) A china (pottery) pipe of the U.S.S.R. (7) Early 17th-century Elizabethan pipe of clay

This was the ceremonial method of smoking prevalent in the Antilles when Columbus and his followers reached them, side by side with a common use of the tobacco leaf rolled up and smoked like a cigar. Bernal Diaz, who accompanied Cortez to Mexico, describes the inhalation of tobacco through a tube. But we have much earlier evidence from Mexico. At the ruined city of Palenque, in the southern province of Chiapas, there are the remains of a "Temple of the Cross," which seems to belong to the beginning of the second century A.D. There, on one of two stone slabs on either side of a doorway, is represented a figure of a priest, clad in a jaguar-skin cloak and a headdress representing a mythical bird, who is blowing out a smoke offering through a straight tube. This Palenque sculpture is the work of the Mayas, the mysterious race which preceded the Toltecs and the Aztecs in Mexico. Other Maya sculptures portray the straight smoking tube, both as an emblem in one of the hands of Chac, the god alike of rain-and-thunder and of fertility, and as an apparently ordinary implement for smoking. Lionel Wafer, at the end of the 17th century, speaks of a roll of tobacco, 2 ft. or 3 ft. long and as thick as a man's wrist, being lighted by a boy, and the smoke being puffed into the faces of a company who made funnels of their hands and inhaled it.

Whatever the original use of the straight tube (which is found in a variety of materials—bone, wood, cane, stone of kinds not

too hard to work, and pottery), the use of it as a pipe for tobacco ages before America was discovered by the early European adventurers is well established. The first modification of the type is that found in the burial mounds of the Muskogee Indians, in the southeastern portion of what is now the United States. The tube is bent up at one end, with a widening of the bowl formed by this end. Pipes on these lines were obviously the model for the clay pipe as known to Europe, which is only natural, since the first Europeans to introduce the use of the tobacco pipe into their own countries learned the habit of smoking not from the West Indies, but from the Indians of the eastern mainland.

The next modification of the tube, which is found in Ohio and Virginia in the burial mounds of another Indian tribe, the Algonquins, converts it from a one-piece to a two-piece pipe. Whatever the material used, usually some kind of stone, the stem was liable to be broken, necessitating a makeshift stem, if the bowl was to continue in use. From this the transition is easy to a bowl alone, into which a wooden stem could be inserted.

While the tobacco pipe was thus evolving in North America apparently a two-piece pipe arose independently in South America. In the upper part of the southern continent true pipes were not used, though the Y-shaped tube, of which we have already heard, was employed for inhaling snuff. Otherwise cigar smoking was the ordinary form of indulgence in tobacco. But in South Brazil in 1650 the traveller Jan Nieuhoff found a great Indian tribe smoking pipes with bowls made of nutshells and with stems of reed or hollowed wood. This kind of pipe, with a small bowl, was the prototype of the pipes of Turkey, Persia and the far east, since the Portuguese took it with them from Brazil along their trade route in the old world. Much larger pipes were also used by the same Brazilian tribe, with bowls of stone, clay, or wood, and are found among their descendants, now living on the Upper Amazon.

The two-piece pipe is also found in the steppes of central and western Asia, and the Kalahiri region of South Africa. Both these are woodless countries, scantily inhabited by people mostly nomadic. There earth smoking is found. The most primitive method is to dig a small pit in the ground, to serve as a bowl; to insert a stick through the earth to the bottom of this pit; and then to withdraw the stick, leaving a hollow tube. The smoker has to lie flat on the ground and apply his mouth to the end of the tube. An improvement on this uncomfortable method is the fashioning of a rough bowl of clay above the surface of the ground, with a tube formed as before with the aid of a stick. Such an earth pipe, when dry, can be detached and carried about. The insertion of a separate mouthpiece into the end of the hollow tube would convert it into a two-piece pipe. In quite a different part of the world, among some of the North American Indians, a hollow reed stuck into a bowl made of wet clay is said to serve as an emergency pipe.

The credit of the first invention of the pipe cannot be assigned to any one people nor is it certain that smoke proceeded always from tobacco leaf. There is hemp, which, in many parts of the world at least, long preceded tobacco. There are many herbs, such as henbane, which were commonly used in Europe, for how many centuries we do not know. Opium smoking, on the other hand, is a late development. Early evidence concerning the tobacco pipe comes from America only, for the reason that the tobacco plant is a native of America. The theory that both the plant and the habit of smoking derived originally from Africa and reached the western coast of America by way of the Indian and Pacific oceans, rests on an insufficient basis. Smoking, no doubt, is a custom of great antiquity in Africa; but it is the smoking of hemp, as exemplified notably among the Bushmen of the Kalahiri desert. The evolution in Africa of the pipe for hemp smoking has, so far as we can tell, begun from the earth pit, through the simple tube, to the *Dakka* (hemp) pipe, which is the ancestor of the water pipes of various kinds used for tobacco in the east. Among the Bushmen an animal's horn, generally an antelope's, is used as the water vessel. Among other African tribes oxhorns, gourds, bamboos and wooden stems are to be seen. It was thus the African hemp smokers who gave to the smokers of tobacco this

idea of using a pipe in which fumes should be filtered and cooled by passing through water.

PIPE SPRING NATIONAL MONUMENT. In north-western Arizona, U.S., in the Kaibab Indian reservation, 18 mi. S.W. of Kanab, Utah, the Pipe Spring National monument, covering 40 ac., was established by the federal government on May 31, 1923. A fort and other historic structures were built there by Mormon pioneers, 1869–70, and the area later served as a centre for ranchers and cattlemen. The monument was dedicated as a memorial to the pioneers of the west.

PIPESTONE, a city of southwestern Minnesota, U.S., county seat of Pipestone county, 40 mi. S.W. of Marshall, on the Coteau des Prairies plateau. It is served by the Chicago, Milwaukee, St. Paul and Pacific, Chicago, St. Paul, Minneapolis and Omaha (Chicago and Northwestern system), Chicago, Rock Island and Pacific, and the Great Northern railways.

The population was 5,269 in 1950 and 4,682 in 1940 by the federal census.

There are dairy, poultry, stock and grain farms in the area, and dairy products are manufactured.

Many of the public buildings in Pipestone, such as the library, jail and courthouse, were constructed in part of the red granite quarried there.

An Indian training school was established in Pipestone in 1893, the Pipestone Indian reservation being north of the city.

Pipestone National Monument.—On Aug. 25, 1937, the Pipestone National monument was established by the federal government. A quarry of about 116 ac., from which the Indians obtained materials used in making ceremonial peace pipes, the area was claimed by the Omaha and Sioux tribes for many years, and bitter wars were fought for its possession. It was believed that the site was the place where man was created by the Great Spirit, and the bed of pipestone or catlinite, reddish-coloured or flecked, with quartzite interstratifications, was the flesh of their predecessors. The Indians later agreed to recognize the area as a sacred reservation, and all Indians were permitted to share what became neutral territory.

The famous red stone was first described by the U.S. ethnologist, artist and explorer George Catlin (1796–1872), after whom it was named. The history of the early days of the Indian tribes was carved in hieroglyphics on the quarry wall, and the Indians became known for their skill in carving in catlinite. By modern times, however, the art had become rare among the Indians.

The shrine was mentioned by Henry Wadsworth Longfellow in *Hiawatha* (1855), based on American Indian legends and traditions.

PIPII, a dialect of the Nahuatl or Aztec language. In southern Mexico, Guatemala and western Salvador there are four groups of Indians who speak a Nahuatl dialect, related to but more primitive than Aztec. These four groups are: (1) Pipil of Soconusco; (2) Pipil of the upper Motagua valley; (3) Pipil of Escuintla; and (4) Pipil of Salvador. At the time of the Spanish conquest several explanations of the presence of these Mexican Indians in Central America were given by the natives. It was said that the Aztec emperor, Ahuitzotl (1486–1502), sent colonists to spy out the land and prepare for a never accomplished conquest. This tale fails to account for the large and well-built cities occupied by the Pipil. More generally it is thought that they were Toltec (*q.v.*) who either migrated from Mexico with one of the early priest-kings named Quetzalcoatl, or, more probably, fled after the downfall of the Toltec empire in the 11th century. The Spanish historian Juan de Torquemada in support of the last hypothesis has preserved a significant migration legend. Numerous ruined cities are attributed to the Pipil by archaeologists. Of these the most important are Santa Lucia Cazumalhuapal and Baul in Guatemala and Chalchuapa, Cihuatlan and Tehuacan in Salvador. These sites yield characteristic stone carvings and pottery types. The modern culture of the Pipil varies from village to

village. In general it reflects that of their neighbours such as the Quiché (*q.v.*).

PIPIT, a subfamily of birds having a great resemblance in habits and appearance to the larks (*q.v.*). They differ, however, in several important characters. They are associated with the wagtails (*q.v.*) in the Passerine family Motacillidae. Pipits, of which over 50 species have been described, occur in almost all parts of the world, but in North America are represented by only two species—*Neocorys spraguei*, the prairie lark of the north-western plains, and *Anthus ludovicianus*, the American titlark, which last is nearly allied to the water pipit of Europe, *A. spinolletta*. To English readers the best-known species is the titlark or meadow pipit, *A. pratensis*, a bird abundant on pastures, moors, and uncultivated districts generally; but in some localities the tree pipit, *trivialis* (*A. arboreus*), takes its place, and where it does so it attracts attention by its loud song, which is delivered (as in all the pipits) on the wing. Another species, the rock pipit, *A. obscurus*, scarcely ever leaves the seacoast and is found almost all round the British Isles. The South African genus *Macronyx*, remarkable for the extreme length of its hind claw, differs and has brighter coloration.

PIPPIN or **PEPIN**, the name of three members of the Carolingian family.

PIPPIN I (d. 639), incorrectly called Pippin of Landen, was mayor of the palace of the youthful Dagobert I, whom Clotaire II had placed over the kingdom of Austrasia. He was disgraced when Dagobert became sole king in 629, and had to seek refuge in Aquitaine.

Returning at Dagobert's death (638), he governed Austrasia in Siebert's name, but died the following year.

PIPPIN II (d. 714), incorrectly called Pippin of Herstal, was son of Adalgiselus (son of Arnulf, bishop of Metz) by a daughter of Pippin I, called in later documents Begga. Toward 678 he placed himself at the head of the great nobles in Austrasia to combat Ebroin, the mayor of the palace, and Neustria. After some reverses he gained a great victory after Ebroin's death at the battle of Tertry (687) not far from St. Quentin, which marks the fall of the Merovingians. He appointed one of his grandsons, Theodebald, mayor of the palace of Neustria, reserving for two others (Arnulf and Hugo), the mayoralty of Austrasia.

He made war on the Frisians and defeated their duke Radbod; and part of these people became converts to Christianity. He also defeated the Alamanni, and subdued their country. The only part of Gaul not under his suzerainty was Aquitaine. The plans he had formed for reforming the church and convoking councils were interrupted by his death on Dec. 16, 714.

PIPPIN III (d. 768), the Short, was the younger son of Charles Martel. Before his death in 741 Charles Martel had divided the Frankish kingdom between his two sons Carloman and Pippin, giving Carloman the eastern part and Pippin the western. Since 737 there had been no king in the Frankish realm; in the diplomas the two brothers bear the title of *maiores palatii*, while the chroniclers call them simply *principes*. In 743, however, the mayors decided to appoint a king in the person of Childeric III, who was apparently connected with the Merovingian family. But Childeric was a mere figurehead, and had no power. The two brothers presided over the tribunals, convoked the councils at which the Frankish church was reformed, assembled the host and made war, jointly defeating and subduing Duke Hunald of Aquitaine.

In 747 Carloman unexpectedly abdicated, became a monk, and retired to a monastery near Rome, subsequently founding on Mt. Soracte the monastery of St. Silvester. From the time of the abdication Pippin was sole master; and in 751, after consulting Pope Zacharias, he held an assembly of the Franks at Soissons,

took the title of king and removed the feeble Childeric to a monastery. He then got himself crowned by St. Boniface, a ceremony which was new to France and which gave the sovereign immense prestige; henceforth the king of the Franks called himself *Gratia Dei rex Francorum*.

Pippin's reign is marked by many important events. He received in France a personal visit from Pope Stephen II, who conferred on him the title of Patrician of the Romans and recrowned him. In return for these honours Pippin, at the appeal of the pope, made two expeditions into Italy, in 754 and 756; and he became the veritable creator of the papal state by conferring on the pope the exarchate of Ravenna, which he had wrested from Aistulf, the king of the Lombards.

Pippin took Septimania from the Arabs, and after a stubborn war of nearly eight years' duration (760-768) succeeded in taking Aquitaine from its duke, Waifer. He also intervened in Germany, where he forced the duke of Bavaria, Tassilo, to become his vassal. In 763, however, Tassilo abandoned Pippin during an expedition against Aquitaine. Pippin made several expeditions against the Saxons, but failed to subdue them. He entered into relations with the eastern empire, exchanging ambassadors with the emperor Constantine Copronymus. During Pippin's reign Frankish institutions underwent some modification. The Frankish assemblies, previously held in the month of March (*champs de mars*), but under Pippin deferred to May (*champs de mai*), came to be more numerous, and served the king of the Franks as a means of receiving the gifts of his subjects and of promulgating his capitularies. At the head of the administration was placed the archchaplain, and an ecclesiastical chancellor was substituted for the ancient *referendarius*. Ecclesiastical reform was continued under Pippin, Bishop Chrodegans of Metz uniting the clergy of Metz in a common life and creating canons. Pippin died on Sept. 24, 768 at St. Denis, leaving two sons, Charles (Charlemagne) and Carloman, between whom he divided his kingdom.

Mühlbacher, *Deutsche Geschichte unter den Karolingern* (1896). (C. Fr.)

PIPRAWA, a village on the Nepalese frontier in the Basti district of Uttar Pradesh, India. This was the site of an ancient stupa (Buddhist religious building) which was opened in 1896. The contents included a large sandstone coffer containing vessels, jewelry and a steatite relic casket. An inscription on one of the vessels has suggested that the stupa was one of those erected for the reception of the ashes of the Buddha. The majority of the finds were placed in the Calcutta museum.

PIPSISSEWA (*Chimaphila umbellata*), called also prince's-pine, a plant of the wintergreen family (Pyrolaceae) flowering from June to August in dry woods in North America from Nova Scotia to British Columbia and southward to Georgia and California. It is found also in Europe and Asia. The flowers are flesh-coloured or pinkish, waxy, five-parted and grow in small terminal groups on a three to ten inch stem. The leaves are dark green, shining, evergreen, sharply toothed and appear in whorls or placed oppositely on the stem. The spotted pipsissewa or spotted wintergreen (*Chimaphila maculata*) occurs in small areas from Maine and Ontario to Minnesota and southward to Georgia and Missouri. Its leaves are dark green, and mottled with white veins, sharply toothed and tapering to narrow points.

PIQUA, a city of Miami co., Ohio, U.S., situated on the Miami river and federal highways 25 and 36; served by the Baltimore and Ohio, the Pennsylvania railways and bus lines. The population in 1950 was 17,447; in 1940, 16,049, federal census. It has grain elevators, large quarries of blue limestone and many diversified manufacturing industries, making textiles, stoves, furniture, blankets, felts and various other articles. On or near the site of Piqua was one of the principal villages of the Chillicothe division of the Shawnee tribe. A town called Washington was laid out in 1807; the present name (that of another division of the Shawnee tribe) was given in 1823. It was chartered as a city in 1850.

PIQUET, a game of cards, probably a development of *romfa*, a game mentioned by Francesco Berni in 1526. The Spanish name of the game was *cientos* (*centum*, a hundred). Piquet was played in England under the name of cent, probably as early as 1550. It is a game of amazing vitality, always in favour with some groups of serious card players.

Piquet is essentially a game for two players, although there are variants for three and four. The pack of 32 cards is used, ranking: ace (high), king, queen, jack, ten, nine, eight, seven. Twelve cards are dealt to each player, two or three at a time. The remaining eight cards, the stock, are spread face down. If either player holds *carte blanche* (a hand with no court card), he announces it and scores 10 points. Nondealer (also called elder, or major) discards from one to five cards and draws an equal number from the top of the stock. If he leaves any of the first five, he may look at them and replace them without showing them to dealer. Dealer (also called younger, or minor) then discards from one card up to the number remaining in the stock and draws an equal number. If he leaves any, he may decide whether or not to turn them face up.

After the draw, nondealer announces his best holding (if any) in each of three classes of scoring combinations. The classes are point, sequence and set. Only one player is entitled to score in a class.

Point is the suit of highest total count, reckoning ace as 11, court cards 10 each and other cards their pip value. Modern usage is to state first the number of cards in the suit. Dealer must reply "good" if his best suit is shorter, "not good" if his is longer, or "how much?" if his suit is equal. In the last case nondealer must state the total count. Whoever has the better point scores 1 for each card in the suit, no score if there is a tie.

A sequence is three or more cards of the same suit in consecutive rank. The French terms are generally used: tierce for sequence of three, quart for four, quint for five, etc. The longest sequence is "good," and the holder may also score any additional sequences he holds. Between equal sequences, that of higher rank is good. Tierce scores 3, quart 4; quint or better scores 10 plus 1 for each card. If there is a tie for best sequence, no sequences are scored.

Sets are three of a kind (trio) or four of a kind (quatorze) of rank ten or higher. A quatorze, counting 14, is good against a trio, counting 3. The player with the highest set may count it and any additional set he holds.

A player may sink (conceal) part or all of a combination if he wishes. Nondealer often sinks a low sequence or trio when he is convinced it is not good. Any declared combination that scores must be proved, usually by exposing it, though etiquette varies in this matter. *Carte blanche* is shown, after the opponent has discarded.

Upon completion of the announcements, nondealer makes the first lead. Each lead requires the other to follow suit if able. The trick is won by the higher card of the suit led. (There is no trump suit.) The winner of a trick leads to the next. For each lead he makes and each trick he wins on an adverse lead, the player counts 1 point; formerly, such a lead or winning card scored only if it was a ten or higher card. The last trick counts 1 extra point. The winner of a majority of the 12 tricks scores 10 points, or 40 for capot if he wins all the tricks. There is no score for cards if the tricks are split 6-6.

If by declared combinations a player reaches 30 points before his opponent scores a point, he jumps from 30 to 90 for repique. If he reaches 30 in declaring and play (excluding capot) before his opponent scores, he jumps to 60 for pique.

During declaration and play, the score is kept verbally, each player announcing his new total after each increment. For example, nondealer has scored 5 for point and 3 for sequence, total 8; dealer has scored 14 for set. Nondealer leads a card and announces "nine." Dealer wins a trick, announces "fifteen," leads a card and announces "sixteen." At the end of play the totals are written on paper.

In the early piquet au cent, a game was continued by alternate deals until one player reached 100 points. This was superseded by

rubicon piquet, in which a game is six deals. The winner receives a bonus of 100 for game, plus the difference of the final totals. But if the loser fails to reach 100 (regardless of whether the winner also is below), he is rubiconed, and the other takes 100 plus the sum of the final totals. Modern players prefer the short game of four deals, the first and last counting double.

BIBLIOGRAPHY.—Sir Henry Jones ("Cavendish"), *The Laws of Piquet and of Rubicon Piquet, Adopted by the Portland Club, With a Treatise on the Game* (1882), *A Guide to Piquet* (1898); E. Culbertson, et al., *Card Games Complete* (New York, 1952).

(A. H. M.D.)

PIRACICABA, a city of the state of São Paulo, southeastern Brazil, on the Piracicaba river, 42 mi. W.N.W. of Campinas and 85 mi. N.W. of São Paulo. The population was 45,782 in 1950.

A railway junction, the city became a centre for brandy distilling and sugar milling, and trade includes coffee and cotton.

An agricultural college was established there.

PIRANDELLO, LUIGI (1867–1936), Italian dramatist, novelist and Nobel prize winner, was born on June 28, 1867, on a country estate near Gerigenti (Sicily). He first went to Rome at the age of 19, staying there until 1891, when he went to Germany and graduated in philosophy at the University of Bonn. He subsequently returned to Rome and taught at the girls' high school until 1923. His first literary essays were in verse, a volume entitled *Mal giocando* published in 1889, followed by a poem *Pasqua di Gea* (1891) and *Elegie renane* (1895). Another Sicilian writer, Luigi Capuana, persuaded him to devote himself to fiction, and in 1901 he published his first novel, *L'esclusa*, in which his somewhat bitter realism already finds expression. Besides the novel, *Il turno*, he began to publish short stories: *Amori senza amore* (1894) *Quando ero matto* (1903), *Befte della morte e della vita* (1902, 1903), *Bianche e nere* (1904), etc. In 1905 his most celebrated novel, *Il fu Mattia Pascal*, appeared, the story of a man, who having shammed being dead, tries in vain to begin his life anew in a different atmosphere and under another name. Other collections of short stories followed: *Erma bifronte* (1906), *La Vita Nuda* (1910), *Terzetti* (1912). He set forth his artistic creed in two volumes entitled *Arte e scienza* (1908). In 1923 his novel, *I vecchi e i giovani*, describing the drama of Italian life after the Risorgimento, was published in the *Rassegna contemporanea*. Other volumes of short stories appeared between 1914 and 1926, such as *La trappola* (1915), *Un cavallo nella luna* (1918), *Il carnevale dei morti* (1919), *Tu ridi* (1920), and another novel *Uno, nessuno e centomila* was published in the *Fiera letteraria*.

In 1920 he said of his own art:

I think that life is a very sad piece of buffoonery; because we have in ourselves, without being able to know why, wherefore or whence, the need to deceive ourselves constantly by creating a reality (one for each and never the same for all), which from time to time is discovered to be vain and illusory . . . My art is full of bitter compassion for all those who deceive themselves; but this compassion cannot fail to be followed by the ferocious derision of destiny which condemns man to deception.

This despairing outlook attained its most vigorous expression in Pirandello's plays. In his youth he had shown a certain contempt for the drama, but in 1912 he was persuaded by the Sicilian playwright, Nino Martoglio, to dramatize one of his own short stories, *La Morsa*, as a one-act piece. His first three-act comedy, *Se non così* (1917), was produced by Marco Parga at Milan in 1913; and then many plays—dramas and comedies—of which the most celebrated are *Il berretto a sonagli*; *Liola* (1917); *Così è se vi pare* (1918); *L'uomo, la bestia e la virtù* (1918); *Ma non è una cosa seria* (1918); *Come prima, meglio di prima* (1920); *Sei personaggi in cerca d'autore* (1918); *L'imbecille*; *Enrico IV* (1922); *Vestire gli ignudi* (1923); *La vita che ti diedi* (1924); *L'altro figlio*; *Ciascuno a suo modo*; *La sagra del signore della nave*; *La giara*.

Pirandello's dramatic art was at first criticized for being too "cerebral," for not seeing life as it really is and for arbitrarily deforming it. The Roman critics first discovered the real meaning of Pirandello's ideology and the human sense of his plays. His main themes are: the necessity and the vanity of illusion, the multiform appearances, all of them unreal, of what is presumed to be the truth, man is not what he thinks he is, but he is "one, no one and a hundred thousand," accordingly as he appears to

this person or to that, and is always different from what he creates himself in his own mind. Hence the supreme catastrophe, when a moral looking glass suddenly reveals to him the image of himself which others see; i.e., what he is to others. Most of Pirandello's plays deal with a lower middle class milieu, peopled with clerks, teachers, lodginghouse keepers, etc., from whose modest vicissitudes he draws conclusions of vast human significance. Typical is *Così è se vi pare*, in which he proves that it is impossible to know the real truth. *Enrico IV* develops in a broader sense; that is, a drama in which we have a man who renounces his changing, empty and vain existence to play the part of a madman, and pretends to believe himself an historical personage, Henry IV. All this might be merely theatrical trickery if it were not seared by a deep anguish, characterizing a philosophy which has destroyed all faith in the absolute, in reality, in any fixed limits outside individual personality.

Pirandello's plays rapidly achieved success throughout Italy and abroad, and were translated into many languages. In 1925 he created an art theatre of his own in Rome, where new Italian and foreign plays are performed, and in the summer of the same year he took his company on a tour to England to produce his own plays in London (at the New Oxford theatre), to Paris, Basle and 18 theatres in Germany.

Pirandello was awarded the Nobel prize in literature in 1934. He died from pneumonia on Dec. 10, 1936. (S. D'A.)

PIRANESI, GIOVANNI BATTISTA (1720–78), Italian draughtsman and etcher, was born in 1720 near Venice, and was educated there and in Rome, where he died in 1778, having settled in the latter city in 1744. His large prints of the buildings of classical and postclassical Rome and its neighbourhood contributed considerably to Rome's fame, and to the growth of classical archaeology and the Neoclassic movement in art.

He developed the medium of etching by means of complicated repeated bitings of the copperplate, which resulted in rich textures and bold contrasts of light and shadow. A prolific etcher, he created more than 1,000 plates. The "Prisons" (*Carceri*) of c. 1745 are his finest early prints; they constitute a climax of late Baroque fantastic, visionary architecture. Among his best mature prints are the series *Le Antichità Romane* (1756), the *Vedute di Roma* (appearing as single prints between 1748 and 1778), and the views of the Greek temples at Paestum (1777–78). In these prints, his unparalleled accuracy of depiction, his personal expression of the structures' dramatic and romantic grandeur, and his technical mastery make them the most original and impressive representations of architecture to be found in western art.

PIRANO, a seaport of Istria, Italy, in the province of Pola, 22 mi. S.W. of the city of Trieste by rail, and from 1947 under Yugoslav administration. Pop. (1936) 5,740 (town), 15,117 (commune). It has picturesque Venetian walls and buildings. On the coast nearby are extensive salt pans. The Venetians defeated the fleet of Frederick Barbarossa off Pirano in 1177. It surrendered to Venice in 1283 and was incorporated with Austria, together with the rest of Istria, in 1813. Under an agreement between Italy and Yugoslavia in Oct. 1954, Pirano continued under Yugoslav control, the former zone B, in which it was located, becoming part of the republic of Slovenia. It was the birthplace of the violinist

Giuseppe Tartini. Near Pirano is the favourite seaside resort of Portorose.

PIRASSUNUNGA, a city of the state of São Paulo, in southeastern Brazil, about 65 mi. N.N.W. of Campinas. The population was 12,546 in 1950.

A railway junction, the city manufactures bricks, cotton textiles and rum.

PIRATE and **PIRACY**. Sir J. Fitzjames Stephen in his *Digest of Criminal Law* defined piracy as follows: "Taking a ship on the High Seas or within the jurisdiction of the Lord High Admiral from the possession or control of those who are lawfully entitled to it and carrying away the ship itself or any of its goods, tackle, apparel or furniture under circumstances which would have amounted to robbery if the act had been done within the body of an English county." (*Cf. A. G. for Hong-Kong v. Kwok-a-Sing*, 1873, L.R. 5 P.C. 179.) Piracy, being a crime not against any particular State but against all mankind, may be punished under international law in the competent court of any country where the offender may be found or into which he may be carried. But, whilst the practice of nations gives to every one the right to pursue and exterminate pirates without any previous declaration of war (pirates holding no commission or delegated authority from any sovereign or state), they may not be killed without trial except in battle. Those who surrender or are taken prisoners must be brought before the proper tribunal and dealt with according to law.

Following the sinking of merchant vessels at sight by German submarines in the World War, by the Washington Treaties (1921-22) between the United States, the British Empire, France, Italy and Japan, attacks upon, and destruction of, merchant vessels upon visit and search by any person in the service of any Power were declared acts of piracy, and such persons may be brought to trial before the civil or military authorities of any Power within the jurisdiction of which he may be found. It was held by the Federal District Court of New York, in the suits brought against the Cunard Steamship company for damages arising out of the sinking at sight of the "Lusitania" by a German submarine, that such sinking was an illegal act. See *The Lusitania* (1918) 251 Fed. 715; *Scott's Cases*, 784-90. (X.)

HISTORY

It is impossible to say at what period in the world's history piracy began. References to this form of robbery occur in early literature. It was rampant in the Mediterranean in the days of the Roman republic, and it is recorded that Julius Caesar, when a young man, fell into the clutches of a gang of sea-robbers who held him prisoner until ransomed, and that after his release he returned with some soldiers who captured his late gaolers and crucified the whole crew. Amongst the early pirates of which records still exist are the Phoenicians, while there are numerous references to sea-rovers in the Odyssey. Out of the dim North, the Vikings (*q.v.*) are known to have come south to plunder the coasts of Britain, Ireland and France, in A.D. 789 and onwards. For many centuries the north-west coast of Africa was the headquarters of the Barbary pirates (*q.v.*) or Moors, as they were commonly called, who had their chief strongholds at Algiers, Salé and Tripoli. From these harbours they sailed out to harry passing ships, or plunder the opposite coast of Spain, carrying back their Christian captives to sell as slaves. In spite of numerous punitive attacks, these fierce sea-robbers were not finally stamped out until 1830. All through the Tudor reigns piracy was rampant around the British isles, particularly in the south of Ireland and in the Scilly isles, where safe retreats existed for the pirate and where receivers of plunder were to be found willing to buy the goods that the pirate had to offer.

As in the case of the land thief, the sea thief could not exist without a market for his ill-gotten goods. It would be useless for a pirate to seize a well-laden merchant ship, if he had nowhere he could dispose of his prize. Sir William Monson in his book *Naval Tracts*, records how he was sent in 1605 to search for pirates in the Shetlands and Hebrides. But it was in Ireland where he found what he looked for. At Broad Haven he met

with an Irish gentleman, of the name of Cormat or Cormac, whose house he describes as being the "well-head of all pirates." Here the Irishman lived in great style and trafficked with the pirate captains, many of whom were the lovers of his daughters.

As life became more difficult for the pirates in the home waters, they migrated further afield, where they could practise their calling with less interference. Thus piracy spread to the far-off West Indies, and the coast of New England, and eventually to the Red sea and Madagascar. For many years the latter island was the happy haunt of the pirates, where they lived in security, married native women, and reigned as petty kings. From here they were able to lay heavy toll on passing ships sailing between England and the East Indies.

The natural haunts of the pirates were in archipelagos and indented coasts, and there at one time or another such places as the Greek islands, the Indian ocean, the coast of Cilicia, the British Isles, Norway and the West Indies became their lurking places.

In England itself, up to the 16th century, piracy was not uncommon, and it was no unusual event for the inhabitants of the Cinque ports to sally forth in their small ships and plunder any passing vessel, and on more than one occasion the fleet of New Romney attacked and plundered the ships of its rival, Yarmouth.

The West Indies.—The West Indies were well prepared for practical exploration both geographically and historically. Since the 16th century the buccaneers (*q.v.*) had preyed upon the Spaniard, and there were innumerable hiding-places, hidden bays in uncharted islands, where pirates could meet in safety and divide the spoils and prepare for their next adventure. During the 17th century the island of Tortuga, or Turtle island, off the coast of Hispaniola, became a regular pirate republic. Good markets for stolen plunder were to be found on the New England coast, and in Jamaica and at New Providence island, as well as in Ireland and certain places in the west of England.

Much of the piracy in the West Indies and America was the direct outcome of the Spanish policy of forbidding her colonists the right of trading with foreigners, in spite of her inability to supply their needs herself. Naturally the Spanish Americans were only too eager to buy smuggled goods, at very low prices, and were not likely to be very particular to enquire where the goods came from. England and France also tried to insist on their colonists trading exclusively with themselves, at their own prices, which, combined with the almost total lack of policing by the regular navies, led to wholesale buying of smuggled merchandise, procured by irregular methods. It was not until the reign of William III., about 1700, that workable laws were made for trying pirates, and even then it was often difficult to get a jury to condemn a pirate who was looked upon as a public benefactor. Owing to the difficulty of policing the seas, particularly in distant waters, the custom arose in the reign of Charles I., and continued until that of George I., of granting free pardons to all pirates who would surrender themselves by a certain date. The result was that when things had become too warm for a pirate, he would make his submission to the authorities and receive the royal pardon, and, as soon as ever his booty was spent, resume his old practices. One of the greatest wholesale pardoning of pirates was carried out by Captain Woodes Rogers at New Providence in the Bahamas in 1718. At this time there were more than 2,000 freebooters entrenched in this pirate stronghold, but Rogers dealt so successfully with them that almost all surrendered.

Organization.—The ranks of the pirates were recruited from a type of seafaring man who disliked steady work with its small rewards, and preferred a life of danger, with a prospect of gaining sudden wealth. After every European war ships would be laid up and crews disbanded. There being no honest employment for all these sailors, they were compelled by circumstances to take any employment at sea that offered itself; and as often as not this consisted of signing on in a ship where no questions were asked, and no wages paid, but where every member of the crew took a share of any profits which might accrue from the voyage.

Very often when a pirate captured a merchant ship the crew of the latter were invited to join the pirates. Some would do so

willingly, others only under compulsion. Most pirates when brought to trial pleaded that they had been compelled to join the pirates, and had done so only to save their lives. It often happened that amongst the members of a captured crew there would be some "sea-artist," as a particularly skilful navigator was called, and he would be compelled to sign on whether he wished to or not. A common source of piracy was the privateer, an armed ship that sailed under a letter of marque, which was apt to drift into piracy, when its legitimate prey was not forthcoming, to supply the prize-money which paid the wages of officers and crew. This fact was pointed out by Cotton Mather (*q.v.*), the New England divine, in one of his "hanging sermons" delivered at Boston to condemned pirates. In one which he preached in 1704 called "A Brief Discourse occasioned by a Tragical Spectacle of a Number of Miscreants under Sentence of Death for Piracy," he stated, "the Privateering Stroke so easily degenerates into the Piratical, and the Privateering Trade is usually carried on with an Unchristian Temper, and proves an Inlet into so much Debauchery and Iniquity."

The same view was expressed by Nelson when he declared that all privateers were no better than pirates, although this wide accusation cannot be allowed to include such famous and patriotic privateers as Captain Fortunatus Wright or Commodore Walker. Many a shady privateer was little better than a pirate, and the letter of marque under which he sailed a mere pretence, as in the case of a pirate who plundered Spanish ships in the 17th century, under a commission sold to him by the governor of a Danish West India island, himself a reformed pirate. This document, written in Danish, proved, when translated, to entitle the holder to hunt for goats and wild pigs on the island of Hispaniola and nothing more.

The establishment of a pirate gang usually took one of two forms. The most usual was for a few ringleaders to plot a mutiny on board a merchant ship. At a prearranged signal the mutineers would seize the officers and kill them and any members of the crew who resisted, and throw their bodies overboard.

But many a pirate who eventually rose high in his profession began in a very small way. Often a handful of desperate characters would steal a boat and row or sail along the coast by night, until they surprised the crew of some small schooner, and became masters of her. In this they would venture further afield, until by cunning or force they got possession of a larger ship. The downfall of most pirates was brought about by their utter lack of discipline, for, unless the elected captain was a man of unusual strength of character, as was the famous Captain Bartholomew Roberts, he was unable to keep his crew in order, and sooner or later, disaster overtook them, through careless navigation or at the hands of a better-disciplined hostile ship.

One of the first formalities of a newly created pirate crew was the drawing up and signing of the ship's articles, which would include such rules as the following, taken from those of Captain John Phillips of the "Revenge":

1. Every man shall obey civil Command; the Captain shall have one full Share and a half in all Prizes; the Master, Carpenter, Boat-swain and Gunner shall have one Share and a quarter.

6. That Man that shall snap his Arms, or smook Tobacco in the Hold without a cap to his Pipe, or carry a Candle lighted without a Lanthorn, shall receive Moses's Law (that is 40 Stripes lacking one) on the bare Back.

9. If at any time you meet with a prudent Woman, that Man that offers to meddle with her, without her Consent, shall suffer present Death.

Another matter, considered to be of great importance, was the choice of a flag, whose chief object was to "strike terror into all beholders." The favourite design was a skull and cross-bones; though sometimes a whole skeleton was depicted, holding in one boney hand a rummer or glass of punch, and in the other a sword or dagger. Whenever possible the pirates carried a surgeon, who was treated with a certain amount of respect.

Famous Characters.—The ordinary pirate was merely a criminal who lived for himself alone, and lacked any sense of ambition other than to get rich quickly, and must not be placed in the same category with the Vikings, who although sea-robbers

and murderers, worked in large and, to a certain extent, organized bands; as did the Mediterranean pirates in Roman times who formed a highly organized brotherhood of desperadoes. The ordinary pirates boasted that they "declared war upon the whole world" and possessed no honour even amongst themselves.

A few of the most famous pirates may be briefly mentioned. Captain John Avery, *alias* Every, *alias* Bridgeman, familiarly known as "Long Ben" or the "Arch-Pirate," was born at Plymouth about 1665, took to the sea and rose to mate in a merchant ship; headed a mutiny and was elected captain; proved himself a daring pirate leader, and after much success off the Guinea coast and in the West Indies sailed to the Red sea, where he seized a rich ship of the Great Mogul, reported to have on board 100,000 pieces of eight and the Mogul's young and lovely daughter. He took both to Madagascar where he settled down as a reigning monarch. In 1696 he was at Boston, where he bribed the governor to allow him and his crew to land and dispose of their plunder. He died in poverty at Bideford after being tricked out of his ill-gotten gains by certain merchants of Bristol. Charles Johnson wrote a play called *The Successful Pyrate*, which was acted at Drury Lane, in 1713, and which was modelled on Avery's career.

Bartholomew Roberts was, perhaps, the greatest of all pirates. Born in Wales in 1682, he died fighting in 1722. He was credited with having taken over 400 ships during his career, and was remarkable for his discipline, for being a teetotaler, and allowing no women or gambling aboard his ships.

Edward Teach, *alias* Blackbeard, a picturesque blackguard, was killed on Nov. 22, 1718, in a hand-to-hand combat with Lieut. Robert Maynard, of H.M.S. "Pearl."

Captain Misson, a Frenchman of good family, was unique in combining active piracy with socialistic ideals. He reigned for many years over a Utopian republic in Madagascar.

Two women pirates, Anne Bonny and Mary Read, deserve mention, as both rose high in their ancient dual professions.

The famous Captain Kidd (*q.v.*) may perhaps have been no pirate at all, but the victim or scapegoat of political intrigue.

With the peace of 1815 came a great increase in West Indian piracy, which was assisted by the inability of the Spanish authorities to cope with the pirates while their colonies were seething with revolt. At last the British and American navies combined to root out the evil once and for all in the Atlantic, although piracy lasted in the Greek islands until nearly 1850.

The end of piracy, after centuries, was brought about by public feeling, backed up by the steam-engine and telegraph. The last relic exists to-day in China, where a nest of troublesome pirates still carries on the old trade in spite of the navies of the foreign powers. The Chinese pirates ship themselves as ordinary coolie passengers on a coastal steamer and, at a given signal, produce revolvers and hold up the officers and crew and compel them to navigate the ship to their headquarters at Bias bay, where the ship is plundered and officers and passengers held for ransom.

BIBLIOGRAPHY.—Mommson's *History of Rome*; Monson's "Naval Tracts" in *Churchill's Voyages*, v., 5 (London, 1744-46), and in *Navy Record Society* (1902); *State Trials*, vols. xiii., xiv., xv. (London, 1812); Captain Charles Johnson's *General History of the Pyrates* (1724) gives full and accurate details of the lives, activities and death of the most notorious pirates of the early 18th century; and a second volume, published in London in 1726, does the same for the Madagascar pirates. It used to be said that Charles Johnson was inaccurate and unreliable, but recent research has proved again and again that, whoever he was, he had first-hand knowledge of his subject and is to be relied upon in almost every detail. (P. Go.)

PIRELLI, LTD. and SOCIETÀ ITALIANA PIRELLI OF MILANO, Italy, are now one of the largest industrial organizations throughout all Italy, with a large number of international associations, employing at the end of 1938 more than 30,000 all over the world, specializing in the manufacture of electric cables, tires of all descriptions, rubber footwear and general india-rubber and gutta-percha goods. Founded in 1872 by Ing. Giovanni Battista Pirelli, they have gradually increased in importance, developing large factories in Italy. Pirelli own or have controlling interests

in other branches connected with the rubber and cable industries, such as cotton-spinning and weaving mills, special rayon mills and copper drawing mills. The Pirelli concerns outside Italy are controlled by a Swiss holding company, the Pirelli Holding S.A., in which the Italian company has a minority interest, but to which it gives its technical collaboration. The said manufacturing concerns are in Spain, Belgium, the Argentine, Brazil and Great Britain, while a Netherlands Indies subsidiary owns a rubber plantation in Java. Financial and commercial Pirelli companies operate also from Brussels, Bucharest, Belgrade, Copenhagen and Alexandria, and Pirelli agents are active in practically every commercial centre throughout the world. In Great Britain, Pirelli General Cable Works, Ltd., London, with factories in Southampton and Eastleigh, are among the most prominent British manufacturers of electric cables; Pirelli Ltd. owns a factory at Burton-upon-Trent, manufacturing pneumatic tires and rubber footwear. These English factories employ British labour throughout. The Pirelli companies specialize in transatlantic submarine telegraph cables, underground cables for abnormal working pressures and pneumatic tires.

(M. S. L.; X.)

PIRENNE, HENRI (1862-1935), Belgian historian, was born at Verviers on Dec. 23, 1862. He first lectured at the University of Liège, and was professor at the University of Ghent, 1886-1930. His *Histoire de Belgique*, of which seven volumes had appeared in 1932, completely revolutionized the current conceptions of Belgian history and nationality by showing how, from the time of the Germanic invasions, Flemings and Walloons were drawn together by community of tradition and economic interest. Pirenne's works on mediaeval cities and social conditions include *Les anciennes démocraties des Pays-Bas* (1910, Eng. trans. 1915), *Recueil des documents relatifs à l'histoire de l'industrie drapière en Flandre* (with G. Espinas, 4 vols., 1906-24) and *Mediaeval Cities: Their Origins and the Revival of Trade* (Princeton, 1925). He was the first president of the "Union Académique Internationale" (1920-23) and received many foreign honours.

PIRKE ABOTH, lit. Chapters of the Fathers, a collection of proverbs arranged chronologically and giving a *catena* of Jewish scholars. The treatise belongs to the IVth Order (*Neziqin*) of the Mishnah and deals with the history of tradition. This, the so-called Oral Law (*Torah she-be-al Peh*, Deut. iv, 14: v, 22-33, especially 31; and other passages) supplemented the Written Law (*Torah she-be-khetav*). The Oral Law in Aboth is traced back from Moses, through Joshua, the elders and Prophets, to the Men of the Great Synagogue, a body the existence of which is now merely doubted but which was formerly denied categorically. Through Simon the Just (either Simeon, grandson of Jaddua, High priest, 310-291 B.C., or his grandson, 219-199) and Antigonus of Socho, both survivors of the Great Synagogue, tradition is carried on by five pairs of teachers (*Zugōth, זוגות*) to Hillel and Shammai (30 B.C.). Henceforward the sayings of their disciples and successors are given until ch. iv, which concludes with El'azarhaq-Qappar (end of 2nd cent. A.D.). Chapters iii and iv are not strictly chronological. Chapters v and vi are of later date. Chapter v combines historical, legendary and didactic elements, miracles are explained and a series of things, sayings and qualities are grouped numerically, e.g., ten *Ma'ammoth* or *Logoi* are said to have created the world; vi is called the "chapter of the acquisition of the Law" and was probably added for liturgical purposes. Aboth is written in simple Hebrew. The aphorisms are of great intrinsic beauty and are of extreme historical importance not only for Judaism but for the environment of nascent Christianity. The chapters are read, on different occasions, in most Jewish rites.

BIBLIOGRAPHY.—Pirke Aboth may be studied in English in Singer's *Authorized Daily Prayer Book* pp. 184 sqq. I. Abrahams Notes (pp. clxxvi of the annotated edition should be consulted). The reader is also referred (a) to the *Jew. Enc.* s.v. *Abot*. (b) *Abot in Encyclopaedia Judaica* vol. I, Berlin (1928). (c) R. Travers Herford's two editions (1) in R. H. Charles *Apocrypha and Pseudepigrapha*, vol. II (1913) and (2) publ. by *Jewish Inst. of Religion Press* (1925), on which see S. B. Maximon's article on pp. 325 sqq. of *Jewish Studies in Memory of Israel Abrahams* (1927). The older editions of C. Taylor and H. Strack are still of great value.

PIRMASENS, a town of Germany, in the Bavarian Palatinate, 40 mi. W. by S. of Speyer, on the railway from Biebermühle. Pop. (1939) 51,578. The staple industry is the production of boots and shoes; but organs, leather and machines are also manufactured.

Pirmasens owes its name to St. Pirmin, who is said to have preached Christianity there in the 8th century. It originally belonged to the count of Hanau-Lichtenberg, but passed to Hesse-Darmstadt in 1736. From 1794-1816 Pirmasens was French; in 1816 it came to Bavaria. In the fall of 1923 Pirmasens was a centre of the separatist movement. In the ensuing civil war 15 separatists were massacred at Pirmasens. (See RHINELAND, THE.)

PIRNA, a town of Germany in the *Land* of Saxony, on the left bank of the Elbe, 11 mi. above Dresden, and on the railway to Bodenbach and Prague. Pop. (1939) 36,130. Pirna, a Slavonic settlement, was for years in the alternate possession of Bohemia and Meissen, but it became permanently united with the latter, and thus with Saxony, in 1405. The most notable edifices are the Gothic parish church, built in the 16th century and restored in 1890, and the old town hall. There are manufactures of glass, machinery, cigars, pottery, slates and enamelled goods and cotton spinning and wood sawing. The Sonnenstein, a fortress above the town, was erected in the 16th century.

PIROGUE or **PIRAGUA** (the French and Spanish forms, respectively, of a Caribbean word for this type of vessel; it has at various times taken many corrupt forms, e.g., *periagua*, *pettiagua*, *pettyoagar*), originally the native name of a vessel made by hollowing out the trunk of a tree, a "dug-out"; hence applied to many different developments of this type of vessel used in the West Indies and along the American coast. An early improvement was to split the "dug-out" into two sections and insert a flat bottom of planking to widen it; another form had a lee-board, was decked in at either end, and had two masts.

PIRON, ALEXIS (1689-1773), French epigrammatist and dramatist, was born at Dijon on July 19, 1689. His father, Aimé Piron, an apothecary, wrote verse in the Burgundian patois. Alexis began life as clerk and secretary to a banker, and then studied law. In 1719 he went to Paris. In that year jealousy of the regular actors produced an edict restricting the Théâtre de la Foire, or licensed booths at fair times, to a single character on the stage, and Piron made a great success with a piece called *Arlequin Deucalion*, representing Deucalion immediately after the Deluge. In 1728 he produced *Les Fils ingrats* (known later as *L'École des pères*) at the *Comédie Française*. He attempted tragedy unsuccessfully in *Callisthène* (1730), *Gustave Vasa* (1733) and *Fernand Cortès* (1744). Piron returned to comedy with *La Méromanie* (1738). His most intimate associates at this time were Mlle. Quinault, the actress, and her friend Marie Thérèse Quenaudon, known as Mlle. de Bar whom he married in 1741. He died on Jan. 21, 1773. His best title to remembrance lies in his epigrams. The burlesque epitaph on himself, in which he ridicules the Academy—

Ci-gît Piron, qui ne fut rien,
Pas même académicien

is well-known. Grimm called him a "machine à saillies."

Piron published his own theatrical works in 1758, and after his death his literary executor, Rigoley de Juvigny, published his *Oeuvres complètes*. M. Bonhomme produced a critical edition in 1859, completed by *Poésies choisies et pièces inédites* in 1879.

PIROT, a town of South Serbia, Yugoslavia. Pop. (1931) 11,238. It lies amid romantic scenery, and is the seat of a prefecture and a tribunal. The inhabitants are engaged in the manufacture of jewellery, thin cloth, woollen braid and carpets. The latter, woven on hand looms by women and children, are its speciality, and are noted for their excellent quality, designs and colouring. There are several schools, a large mosque and a curious old square leaning tower. The mediaeval fortress is believed to have been also built on the site of the Roman fortress Quimedava, on the military road from Old Naissus (Nish) to Philippopolis. Outside the town is an early modern entrenched camp. Pirot, which is strategically important, was captured by the Serbs in the Russo-Turkish War (1877-78) and was ceded to Serbia by the Treaty of Berlin (1878). In the war between Serbia and Bulgaria in 1885 Pirot was

occupied by the Bulgarians and held by them till peace was signed. It was again occupied by Bulgaria in 1941.

PIRRIE, WILLIAM JAMES, 1ST VISCOUNT (1847–1924), British shipbuilder and engineer, was born at Quebec on May 31, 1847, and educated at Belfast Royal Academic institution. In 1862 he entered the shipbuilding firm of Messrs. Harland and Wolff of Belfast, becoming partner in 1874 and later chairman. His firm built the White Star line steamships, the first being launched in 1870. From 1896 to 1897 he was lord mayor of Belfast. In 1906 he was raised to the peerage as Baron Pirrie. In 1918, towards the close of World War I, he was made controller-general of merchant shipping. In 1921, on the king's visit to Belfast to inaugurate the new parliament of Northern Ireland, he was created a viscount. He died on June 6, 1924.

PISA, a town and archiepiscopal see of Tuscany, Italy, capital of the province of Pisa, on the Arno, 7 mi. from the sea, and 49 mi. W. of Florence by rail. Pop. (1936) 49,471 (town), 72,468 (commune). It retains its mediaeval walls, 6½ m. in circuit; the citadel now contains barracks. The cathedral, the baptistery, and the famous leaning-tower form a group by themselves at the north-west corner of the town. The two former are built in black and white marble, a characteristic found in Pisan churches elsewhere also. (See *SARDINIA*.)

The architects of the cathedral were Buschetto and Rinaldo, both probably Pisans. The church is in plan a Latin cross, 311½ ft. long and 252 ft. wide across the transepts inside. The nave, 109 ft. high, has double, the transepts single, vaulted aisles; and at the intersection of nave and transepts is a dome. The columns of the nave and side aisles are ancient. The west front is the finest part of the exterior: the range of arches running round the base is repeated by four open arcades. The three bronze doors were re-made after the fire of 1596; that of the south side (1180) is by Bonanno. The mosaics in the apse were designed by Cimabue, and the splendid decagonal pulpit (restored in 1926: see *Per la ricostruzione del per-*

gamo di Giovanni Pisano, 1926) is by Giovanni Pisano. The baptistery, begun in 1153, is a circle 100 ft. in diameter and is covered with a cone-surmounted dome 190 ft. high on which stands a statue of S. Ranieri. The lowest range of semicircular arches consists of 20 columns, and the second of 60; and above this is a row of 18 windows in the same style separated by as many pilasters. In the interior, which is supported by four pilasters and eight columns, the most striking features are the octagonal font and the hexagonal pulpit, erected in 1260 by Nicola Pisano. The campanile or "leaning tower of Pisa," begun by Bonanno in 1174, is round. The walls at the base are 13 ft. thick, and at the top about half as much; they are constructed throughout of marble. The basement is surrounded by a range of semicircular arches supported by 15 columns, and above this rise six arcades with 30 columns each. The eighth storey, which contains the bells, is of much smaller diameter than the rest of the tower, and has only 12 columns. The height of the tower is 179 feet. The tower was 15½ ft. out of the perpendicular when measured in 1829, and 16½ ft. in 1910. There is no reason to suppose that the architects intended that the campanile should be built in an oblique position; it would appear to have assumed it while the work was still in progress. The foundations are not more than 10 ft. deep, and their circum-

THE LEANING TOWER OF PISA
Begun in 1174 and completed in 1350, the campanile is 179 ft. high and leans more than 16 ft. out of the perpendicular

ference only that of the tower. The Campo Santo, lying to the north of the cathedral, owes its origin to Archbishop Ubaldo (1188–1200) who made the spot peculiarly sacred by bringing 53 shiploads of earth from Calvary. The building, erected in the Italian Gothic style by Giovanni Pisano in 1278–83, is of special interest for its famous frescoes by various Tuscan artists, including a "Last Judgment" by Francesco da Volterra after Orcagna (1370–71); Benozzo Gozzoli (23 Old Testament scenes, 1468–84), and also for the large collection of Roman sculptures which it contains. Other notable churches are: S. Andrea, S. Pierino, S. Michele in Borgo (11th century), S. Sepolcro, erected by Diotisalvi (c. 1150), S. Nicolò, with a four-storied tower (c. 1230), S. Caterina (1252), S. Francesco (13th century) with frescoes by Taddeo Gaddi (in the adjacent monastery is the interesting museum and picture gallery); S. Maria della Spina, an elegant little church of white marble (1325–29); and the Renaissance church of the Tuscan order of St. Stephen from plans by Vasari (after 1562), who also reconstructed the palace of the order.

The main streets of the older part of the town have porticoes. There are wide quays, with fine buildings, on each side of the Arno, but the town, as a whole, is quiet, owing much of its importance to its being the junction for Florence, Lucca, and Volterra, on the main line between Rome and Genoa. The university, founded in 1338, had 1,500 students in 1938–39; it has a natural history and other museums and a botanical garden. There is also an engineering school, a veterinary institute and an agricultural institute. In the vicinity are the royal villa and stud-farm (horses and dromedaries) of San Rossore (the name is a corruption of Lussorio), and the mineral baths of San Giuliano, alkaline-ferruginous, with temperature 91.4° to 105.8° F. At the mouth of the Arno, joined to the city by a steam tramway (on the way is the old church of S. Piero in Grado) is the seaside resort of Marina di Pisa, also known as Bocca d'Arno, a well-known centre for landscape painters.

At Navacchio, 5 mi. E. of Pisa, is a biscuit factory, 4 mi. N. of which is Calci, and near it the large monastery of the Certosa di Pisa.

The ancient Pisae on the right bank of the Arno was only 2 m. from the sea, the delta having increased since. It is believed to have been founded from Pisae in Elis and is first mentioned in history as the place at which a Roman army from Sardinia landed in 225 B.C. Being situated on the coast road (Via Aemilia), it was important as a frontier fortress against Liguria, for the fertility of its territory, and its quarries and timber for shipbuilding. Scanty ruins of Roman baths exist near the modern Lucca gate on the north. The older town occupied the same site. (T. A.)

HISTORY

Little is known of Pisa during the barbarian invasions, but it is an ascertained fact that it was one of the first towns to assert its independence of Byzantine rule. During the first years of the Lombard rule the necessity of defending the Italian coast from the attacks of the Byzantines was favourable to the development of the Pisan navy.

Early Wars.—In 1003 we find records of a war between Pisa and Lucca, which, according to Muratori, was the first waged between Italian cities in the middle ages. But the military development and real importance of Pisa in the 11th century must be attributed to the continuous and desperate struggle it maintained against the tide of Saracenic invasion from Sicily. Numerous legends and fables of the old chroniclers serve to attest the importance of Pisa in those days. The Saracens repeatedly attacked the town, but were repulsed, and the Pisans themselves assumed the offensive in Calabria, Sicily, and even in Africa. In 1015 a memorable expedition was undertaken by the united forces of Pisa and Genoa against Mogahid, better known in the Italian chronicles as Mugeto, whom they drove from Sardinia. Again invading the island, he was again attacked and defeated by the same adversaries, leaving a brother and son, or, as some authorities aver, a wife and son, prisoners in their hands. Sardinia continued to be governed by native "judges" who were like petty sovereigns, but were now subject to the sway of Pisa. This was

the primary cause of the jealousy of the Genoese and of the wars afterwards made by them upon Pisa. Meanwhile the Pisans flourished more and more, and continued hostilities against the Saracens. In 1062 their ships returned from Palermo laden with spoil. Thus it is not surprising that Pisa should already have had its own code of laws (*Consuetudini di mare*), which in 1075 were approved by Gregory VII., and in 1081 confirmed by a patent from the emperor, Henry IV. The oldest of Pisan statutes still extant is the *Breve dei consoli di mare* of 1162.

Commercial Prosperity.—In 1099 the Pisans joined in the second crusade, proved their valour at the capture of Jerusalem, and derived many commercial advantages from it; for within a short time they had banks, consuls, warehouses and privileges of all kinds in every Eastern port. Thus while the commune of Pisa was still under the rule of the marquises of Tuscany, all negotiations with it were carried on as with an independent state officially represented by the archbishop and consuls. The aristocrats were the dominant party, and filled the highest offices of the republic, which, in the 12th century, rose to great power, both on sea and land, by its wars with the Lucchese, Genoese and Muslims. In the years 1113 and 1115 it achieved a still greater enterprise. The Pisan fleet of 300 sail, commanded by the archbishop, Pietro Moriconi, attacked the Balearic Isles, where as many as 20,000 Christians were said to be held captive by the Muslims and returned loaded with spoil and with a multitude of Christian and Muslim prisoners. The former were set at liberty or ransomed, and among the latter was the last descendant of the reigning dynasty. Immediately afterwards, the 14 years' war with Genoa broke out. The two republics contested the dominion of the sea, and both claimed supreme power over the islands of Corsica and Sardinia. A papal edict awarding the supremacy of Corsica to the Pisan Church proved sufficient cause for the war, which went on from 1118 to 1132. Then Innocent II. transferred the supremacy over part of Corsica to the Genoese Church, and compensated Pisa by grants in Sardinia and elsewhere. Accordingly, to gratify the pope and the emperor, Lothair II., the Pisans entered Neapolitan territory to combat the Normans. They aided in the vigorous defence of the city of Naples, and twice attacked and pillaged Amalfi, in 1135 and 1137, with such effect that the town never regained its prosperity. The war with Genoa never came to a real end. Even after the retaking of Jerusalem by the Muslims (1187) the Pisans and Genoese again met in conflict in the East, and it was plain that there could be no lasting peace between these rival powers until the one or the other should be crushed. The greatness and wealth of the Pisans at this period of their history is proved by the noble buildings by which their city is adorned. The foundations of the cathedral were laid in 1063, and its consecration took place in 1118; the baptistry was begun in 1152, and the campanile (the famous leaning tower) in 1174. And all three magnificent structures were mainly the work of Pisan artists, who gave new life to Italian architecture, as they afterwards renewed the art of sculpture.

RIVALRY WITH FLORENCE AND GENOA

The chief authority was still vested in the nobles, who, both in Pisa and in Sardinia, exercised almost sovereign power. They formed the real strength of the republic, and kept it faithful to the empire and the Ghibelline party. The Guelph and popular element which constituted the force and prosperity of Florence was hostile to Pisa, and led to its downfall. Owing to the political and commercial interests binding Florence to the Roman court, the Guelph element naturally prevailed there, while growth of its trade and commerce necessarily compelled that republic to encroach on waters subject to Pisan rule. And, although Pisa had hitherto been able to oppose a vigorous resistance to Genoa and Lucca, it was not so easy to continue the struggle when its enemies were backed by the arms and political wisdom of the Florentines, who were skilled in obtaining powerful allies. The chroniclers ascribe the first war with Florence, which broke out in 1222, to a ridiculous motive. The ambassadors of the rival states in Rome are said to have quarrelled about a lapdog—which merely shows that there were already so many general

and permanent reasons for war that no special cause was needed to provoke it. In 1228 the Pisans met and defeated the united forces of Florence and Lucca near Barga, in the Garfagnana, and at the same time they despatched 52 galleys to assist Frederick II. in his expedition to the East. Shortly after this they renewed hostilities with the Genoese on account of Sardinia, and war was intermittent down to 1259, when it terminated in the decisive victory of the Pisans and the consolidation of their supremacy in Sardinia. But meanwhile Florence had made alliance with Genoa, Lucca and all the Guelph cities of Tuscany against its Ghibelline rival: the pope had excommunicated Frederick II. and all his adherents; and, as a crowning disaster, the death of Frederick in 1250 proved a mortal blow to the Italian Ghibelline cause. Nevertheless the Pisans were undaunted. Summoning Siena, Pistoia and the Florentine exiles to their aid, they boldly faced their foe, but were defeated in 1254. Soon after this date we find the old aristocratic government of Pisa replaced by a more popular form. Instead of the consuls there were now 12 elders (*anziani*); besides the podestà, there was a captain of the people; and there was a general council as well as a senate of 40 members. The rout of the Tuscan Guelphs on the field of Montaperti (1260) restored the fortunes of Pisa. But the battle of Benevento (1266), where Manfred fell, and the rout of Tagliacozzo (1268), sealing the ruin of the house of Hohenstaufen in Italy and the triumph of that of Anjou, were fatal to Pisa. For the republic had always sided with the empire and favoured Conradin, whose cruel end struck terror into the Ghibelline faction. The pope hurled an edict against the Pisans and tried to deprive them of Sardinia, while their merchants were driven from Sicily by the Angevins. The internal condition of the city was affected by these events. Owing to the increasing influence of the Guelph and popular side, to which the more ambitious nobles began to adhere for the furtherance of personal aims, the aristocratic Ghibelline party was rapidly losing ground. At this time Count Ugolino della Gherardesca had become the virtual head of the republic, and, in order to preserve its independence and his own sway, inclined to the Guelphs and the popular party, in spite of the Ghibelline traditions of his race. He was supported by his kinsman, Giovanni Visconti, judge of Gallura, in Sardinia; but almost all the other great families vowed eternal hatred against him, and proclaimed him a traitor. In 1274 he and Visconti were driven into exile. Both then joined the Florentines, took part in the war against their native city, and laid waste its surrounding territories. In 1276 the Pisans were compelled to agree to very grievous terms—to exempt Florentine merchandise from all harbour dues, to yield certain strongholds to Lucca, and to permit the return of Count Ugolino. Thus the count again became a powerful leader in Pisa. Visconti, however, was dead.

This was the moment chosen by Genoa for a desperate and decisive struggle with her perpetual rival. For some years the hostile fleets continued to harass each other and engage in petty skirmishes, as if to measure their strength and prepare for a final effort. On Aug. 6, 1284, at the great battle of Meloria 72 Pisan galleys engaged 88 Genoese, and half the Pisan fleet was destroyed. The chroniclers speak of 5,000 killed and 11,000 prisoners; and, although these figures must be exaggerated, so great was the number of captives taken by the Genoese as to give rise to the saying—"To see Pisa, you must now go to Genoa." This defeat crushed the power of Pisa. She had lost her dominion over the sea, and the Tuscan Guelphs again joined in attacking her by land. Count Ugolino had taken part in the battle of Meloria and was accused of treachery. At the height of his country's disasters he sought to confirm his own power by making terms with the Florentines, by yielding certain castles to Lucca and by neglecting to conclude negotiations with the Genoese for the release of the prisoners, lest these should all prove more or less hostile to himself. This excited a storm of opposition against him. The archbishop, Ruggieri, having put himself at the head of the nobles, was elected podestà by the Lanfranchi, Sismondi and Gualandi, and a section of the popular party. The great bell of the commune called together the adherents of the archbishop; the bell of the people summoned the partisans of the count. After

a day's fighting (July 1, 1288) the count, his two sons and his two grandsons were captured in the palazzo del popolo (or town hall), and cast into a tower belonging to the Gualandi, and known as the "Tower of the Seven Streets." Here they were all left to die of hunger. Their tragic end was afterwards immortalized in the *Divina Commedia*. The sympathies of Dante Alighieri, the Florentine patriot and foe of Rome, were naturally in favour of the victims of an aristocratic prelate opposed to all reconciliation with Florence.

The Florentines were now allied with Lucca and Genoa, and a few of their vessels succeeded in forcing an entry into the Pisan port, blocked it with sunken boats, and seized its towers. In 1293 they secured a profitable peace. They and the other members of the Guelph league were freed from all imposts in Pisa and its port. In addition to these privileges the Genoese also held Corsica and part of Sardinia; and throughout the island of Elba were exempted from every tax. They likewise received a ransom of 160,000 florins for their Pisan prisoners.

In 1312 the arrival of the Emperor, Henry VII., gladdened the hearts of the Pisans, but his sudden death in 1313 again overthrew their hopes. He was interred at Pisa, and Uguccone della Faggiuola remained as imperial lieutenant, was elected podestà and captain of the people, and thus became virtual lord of the city. As a Ghibelline chief of valour and renown he was able to restore the military prestige of the Pisans, who under his command captured Lucca and defeated the Florentines at Montecatini on Aug. 29, 1315. In 1316, however, he was expelled in an outburst of popular fury. But Pisa's freedom was forever lost. Uguccone della Faggiuola was succeeded by other lords or tyrants of whom the most renowned was Castruccio Castracani, a political and military adventurer of much the same stamp as Uguccone himself. With the help of Louis the Bavarian, Castruccio became lord of Lucca and Pisa, and was victorious over the Florentines; but his premature death in 1328 again left the city a prey to the conflicts of opposing factions. New lords, or petty tyrants, rose to power in turn during this period of civil discord, but the military valour of the Pisans was not yet extinguished. By sea they were almost impotent—Corsica and Sardinia were lost to them forever—but they were still formidable by land. In 1341 they besieged Lucca in order to prevent the entry of the Florentines, to whom the city had been sold for 250,000 florins by the powerful Mastino della Scala. Aided by their Milanese, Mantuan and Paduan allies, they gave battle to their rivals, put them to rout at Altopascio (Oct. 2), and then again excluded them from their port. Thereupon the Florentines obtained Porto Talamone from Siena and established a navy of their own. By this means they were enabled to capture the island of Giglio, and, attacking the Pisan harbour, carried off its chains, bore them in triumph to Florence, and suspended them in front of the baptistery, where they remained until 1848. Then in pledge of the brotherhood of all Italian cities, they were given back to Pisa, and placed in the Campo Santo.

The war was now carried on by the free companies with varying fortune, but always more or less to the hurt of the Pisans. In 1369 Lucca was taken from them by the emperor Charles IV.; and afterwards Gian Galeazzo Visconti, known as the count of Virtù, determined to forward his ambitious designs upon the whole of Italy by wresting Pisa from the Gambacorti. For at this time the conflicts of the Raspanti faction, headed by the Gherardesca, with the Bergolini led by the Gambacorti, had left the latter family masters of the city. At Visconti's instigation Piero Gambacorti, the ruler of the moment, was treacherously assassinated by Jacopo d'Appiano, who succeeded him as tyrant of Pisa, and bequeathed the state to his son Gherardo. The latter, a man of inferior ability and daring, sold Pisa to the count of Virtù, receiving in exchange 200,000 florins, Piombino, and the islands of Elba, Pianosa and Monte Cristo. Thus in 1399 Visconti took possession of Pisa, and left it to his natural son, Gabriele Maria Visconti, who was afterwards expelled from its gates. But even in this century of disaster the Pisans continued to encourage not only commerce, but also the fine arts. In the year 1278 they had entrusted the erection of their fine Campo Santo to Nic-

cola and Giovanni Pisano, by whom the architectural part of it was completed towards the end of the century. In the following year the first artists of Italy were engaged in its decoration, and the celebrated frescoes attributed to Orcagna (*q.v.*) were painted on its walls. Others were afterwards supplied by Benozzo Gozzoli and men of lesser note, and the labour of ornamentation was only discontinued in 1464.

The Victory of Florence.—Meanwhile, in 1406, the Florentines made another attack upon Pisa, besieging it simultaneously by sea and land. Owing to the starving condition of its defenders, and aided by the treachery of Giovanni Gambacorti, they entered the city in triumph on Oct. 9, and sought to "crush every germ of rebellion and drive out its citizens by measures of the utmost harshness and cruelty." Such were the orders sent by the Ten of War to the representatives of the Florentine government in Pisa, and such was then the established policy of every Italian state. Consequently for a long time there was a continual stream of emigration from Pisa. The Medici pursued a humaner course. In 1472 Lorenzo the Magnificent tried to restore the ancient renown of the Pisan university. To that end he filled it with celebrated scholars, and, leaving only a few chairs of letters and philosophy in Florence, compelled the Florentines to resort to Pisa for the prosecution of their studies. But nothing could now allay the inextinguishable hatred of the conquered people. When Charles VIII. made his descent into Italy in 1494, and came to Sarzana on his way to Tuscany, he was welcomed by the Pisans with the greatest demonstrations of joy. And, although that monarch was ostensibly the friend of Florence, they did not hesitate, even in his presence, to assert their own independence, and casting the Florentine emblem, the Marzocco, into the Arno, made instant preparations for war. Between 1499 and 1505 they heroically withstood three sieges and repulsed three attacking armies. But their adversaries always returned to the assault, and, what was worse, yearly laid waste their territories and destroyed all their crops. Soderini, who was perpetual gonfalonier of Florence, and Machiavelli, the secretary of the Ten, urged on the war. In 1509 Florence encamped her forces on three sides of the distressed city, which at last, reduced to extremity by famine, was compelled to surrender on June 8, 1509. Thenceforth the Florentines remained lords of Pisa. But now, mainly owing to the efforts of Soderini and Machiavelli, the conquerors showed great magnanimity. They brought with them large stores of provisions which were freely distributed to all; endeavoured to succour the suffering populace in every way, and gave other assistance to the wealthier classes. Nevertheless, emigration continued even on a larger scale than in 1406, and the real history of Pisa may be said to have ended. In Naples, in Palermo, in all parts of Italy, Switzerland and the south of France, we still find the names of Pisan families who quitted their beloved home at that time. The Florentines immediately built a new citadel, and this was a great bitterness to the Pisans. The Medici, however, remained well disposed towards the city. Leo X. was an active patron of the university, but it again declined after his death. The grand duke, Cosimo I., a genuine statesman, not only restored the university, but instituted the "uffizio dei fossi" or drainage office for the reclamation of marsh lands, and founded the knighthood of St. Stephen. This order played a noble part in the protection of Tuscan commerce, by fighting the Barbary pirates and establishing the prestige of the grand-ducal navy (*see* MEDICI). Under the succeeding Medici, Pisa's fortunes steadily declined. Ferdinand I. initiated a few public works there, and above all restored the cathedral, which had been partly destroyed by fire in 1595. These dreary times are brightened by one glorious name—that of Galileo Galilei.

PISA, COUNCIL OF (1409). The great schism of the west had already lasted 30 years, and the efforts which had been made to restore unity within the church by the simultaneous resignation of the 2 rival pontiffs had been in vain, when in the spring of 1408, the state of affairs being desperate, the idea arose of assembling a council to effect a union without the co-operation of the popes. The initiative came from those cardinals who had one after the other seceded either from Gregory XII or Benedict XIII.

They were forestalled by the popes, who each summoned a council, the former to Cividale (in Friuli), the latter to Perpignan, so the dissident cardinals sent out antedated letters inviting Christendom to assemble at Pisa on March 25, 1409. Their appeal met with a response in a great part of Italy, France, Navarre, Portugal and England, and in Germany in the states subject to Wenceslas, king of the Romans, the electors of Cologne and Mainz, the margrave of Brandenburg, etc. For a time the number of the fathers exceeded 500.

The day after the opening of the council, proceedings were started against the two popes, who, it was agreed, were to be eliminated. An act of accusation, containing in 37 articles the chief complaints against them, was read out to the people; not only their policy, but their orthodoxy was attacked, and there was even an insinuation of sorcery.

That is, in order to depose them with some show of legality, it was necessary, as a preliminary, to convict them of heresy, and it began to be seen that their tenacity of power, and the ruses by which they evaded the necessity of abdicating, however harmful might be their consequences, did not in themselves constitute a clearly defined heresy. On June 5, 1409, was read the definitive sentence: that as heretics, and therefore separated from the church, Pedro de Luna (Benedict XIII) and Angelo Corrario (Gregory XII) were *ipso facto* deposed from any office; they must not be obeyed, nor assisted nor harboured.

In order to complete their task the cardinals present at Pisa, authorized by delegation of the council, shut themselves up in conclave, and elected one of their number, Peter Philarges, cardinal of Milan, as the new pope, who assumed the name of Alexander V. They had hoped to save the church, but unfortunately the result of their efforts, generous as they were, was that the schism increased in bitterness, and that instead of the unity for which the church craved, three popes continued to flourish. Both the deposed pontiffs protested against the legality of the council of Pisa; each had numerous partisans, and the thesis, constructed rather to meet the exigencies of the case, which attributed to a synod assembled by the cardinals the right of constituting itself judge of a sovereign pontiff, was far from being established. The council was proceeding to occupy itself with reform when it was dissolved by Alexander V (Aug. 1409).

PISAN, CHRISTINE DE (1364-c. 1430), French poet, of Italian birth, was born at Venice in 1364. When she was four years old she was brought to her father, a councillor of the Venetian republic, in Paris, where he held office as astrologer to Charles V. At 15 Christine married Étienne du Castel, who became Charles' notary and secretary. After the king's death in 1380 her father lost his appointment, and died soon after; and when Christine's husband died in 1389 she found herself without a protector, and with three children depending on her. This determined her to have recourse to letters as a means of livelihood. Her first ballads were written to the memory of her husband, and as love poems were the fashion she continued to write others — *lais*, *virelais*, *rondeaux* and *jeux à vendre*—though she took the

precaution to assure her readers (*Cent balades*, No. 50) that they were merely exercises. In 1399 she began to study the Latin poets, and between that time and 1405, as she herself declares, she composed about 15 important works, chiefly in prose, besides minor pieces.

The earl of Salisbury, who was in Paris on the occasion of the marriage of Richard II with Isabella of France (1396), took her elder son, Jean du Castel (b. 1384), and reared him as his own; the boy, after Salisbury's death (1400), being received by Philip of Burgundy, at whose desire Christine wrote *Le Livre des faitz et bonnes moeurs du sayge roy Charles* (1405), valuable as a first-hand picture of Charles V and his court. Her *Mutation de fortune*, in which she finds room for a great deal of history and philosophy, was presented to the same patron on New Year's day, 1404. It possesses an introduction of great autobiographical interest. In *La Vision* (1405) she tells her own history, by way of defence against those who objected to her pretensions as a moralist. Henry IV of England desired her to make his court her home, and she received a like invitation from Galeazzo Visconti, tyrant of Milan. She preferred, however, to remain in France, where she enjoyed the favour of Charles VI, the dukes of Berry and Burgundy, the duchess of Bourbon and others.

Christine was a champion of her own sex. In her *Dit de la rose* (1402) she describes an order of the rose, the members of which bind themselves by vow to defend the honour of women. Her *Épître au dieu d'amour* (1399) is a defence of women against the satire of Jean de Meung, and initiated a prolonged dispute with two great scholars of her time, Jean de Montreuil (d. 1415) and Gonthier Col, who undertook the defence of the *Roman de la rose*. Christine wrote about 1407 two books for women, *La Cité des dames* and *Le Livre des trois vertus*, or *Le Trésor de la cité des dames*. She was devoted to her adopted country. During the civil war she wrote a *Lamentation* (1410) and a *Livre de la paix* (1412-13), but after the disasters of the campaign of Agincourt she retired to a convent. We have no more of her work until 1429, when she broke her silence to write a song in honour of Joan of Arc. Of the circumstances of her death nothing is known but it probably took place about this time.

Her poems were edited by Maurice Roy for the Société des anciens textes français (1886 etc.), and her *Livre du chemin du long estude*, by Fuschel (Berlin, 1887). There are monographs by Raimond Thomassy (Paris, 1838); E. M. D. Robineau (Saint-Omer, 1882); and Friedrich Koch (Goslar, 1885). It is possible that Jean Castel, who was chronicler of France under Louis XI, was Christine's grandson. Thomas Hoccleve imitated her *Épître au dieu d'amour*, in his "Letter of Cupid" (*Chaucerian and other Pieces*, ed. W. W. Skeat, 1897). A translation of her *Épître d'Othéa* was made (c. 1440) by Stephen Scrope for his stepfather, Sir John Fastolf, and is preserved in a MS. at Longleat. This was edited (1904) for the Roxburghe club by W. G. F. Warner as *The Epistle of Othéa to Hector, or the Boke of Knyghthode. The Moral Proverbs of Christyne de Pise*, translated by Earl Rivers, was printed in 1478 by William Caxton, who himself translated, by order of Henry VII, her *Livre des faitz d'armes, et de chevalerie*, a treatise on the art of war, based chiefly on Vegetius. Her *Cité des dames* was translated by Brian Anslay (London, 1521).

PISANO, ANDREA (c. 1270-1348), Italian sculptor, was born about 1270, and first learned the trade of a goldsmith. His style was influenced to some extent by Giovanni Pisano. His chief works were executed at Florence, and the formation of his mature style was due rather to Giotto than to his earlier masters. Of the three world-famed bronze doors of the Florentine baptistery, the earliest one—that on the south side—was the work of Andrea; he spent many years on it; and it was finally set up in 1336¹. It consists of a number of small quatrefoil panels—the lower eight containing single figures of the Virtues, and the rest scenes from the life of the Baptist. At the death of Giotto in 1337, Andrea was appointed architect of the campanile, and built the two stories of niches above the work of Giotto. Of the beautiful panel-reliefs which decorate the campanile those representing "The Crane," "Weaving," "Daedalus," "Navigation," "Hercules," "Agriculture," "Theatre" and "Medicine" display the style of Andrea Pisano. The duomo contains the chief of Andrea's other Florentine works in marble. In 1347 he was appointed architect

¹ The date on the door, 1330, refers to the original wax model.

in the duomo of Orvieto, which had already been designed and begun by Lorenzo Maitani. The date of his death must have been shortly before 1349.

Andrea Pisano had two sons, Nino and Tommaso—both, especially the former, sculptors of considerable ability. Nino was very successful in his statues of the Madonna and Child, which were full of human feeling and soft loveliness—a perfect embodiment of the Catholic ideal of the Divine Mother. Andrea's chief pupil was Andrea di Cione, better known as Orcagna (*q.v.*). Balduccio di Pisa, another, and in one branch (that of sculpture) equally gifted pupil, executed the wonderful shrine of S. Eustorgio at Milan—a most magnificent mass of sculptured figures and reliefs.

See M. Reymond, *La Sculpture Florentine* (Florence, 1897).

PISANO, GIOVANNI (c. 1240–after 1314), Italian architect and sculptor, was the son of Niccola Pisano. He developed and extended into other parts of Italy the renaissance of sculpture initiated by his father. He spent the first part of his life as a pupil and fellow worker of Niccola and appears as his collaborator at the fountain of the great piazza at Perugia. Between 1278 and 1283 he was employed on the cloister, which surrounds the Campo Santo at Pisa. In 1284 Giovanni was appointed capo maestro of the new cathedral at Siena. He began the magnificent façade. His design, however, was modified by the architects who succeeded him. From 1298 to 1301 he was employed on the pulpit of San Andrea at Pistoia. Then followed the pulpit of the cathedral at Pisa, completed in 1311. It was taken to pieces about 200 years later, but fragments are to be seen at Pisa, and in the Berlin museum. The figures for the tomb of the Empress Margaret, now in the Palazzo Bianco at Genoa, were executed soon after the empress' death in 1311. A number of statues of "The Virgin and Child" have been attributed to him on stylistic evidence. Among these the three most important are at Prato; in the Campo Santo, Pisa, and in the Arena chapel at Padua. The Cathedral of Pisa has a fine figure of the Madonna carved in ivory. Giovanni's early work was inspired by his father Niccola. Later his figures and draperies displayed the expressive flow of lines appertaining to the Gothic style. Like the work of most stonemasons in mediaeval times, his sculpture forms part of an architectural design. The subject matter of his carving was dictated by the liturgy of the church, and his interpretations are imbued with deep religious feeling.

See M. Sauerlandt, *Bildwerke des Giovanni Pisano*, etc. (1904); A. Brach, *Nicola und Giovanni Pisano und die Plastik des XIV Jahrhunderts in Siena* (1904); I. Supino, *Arte Pisana* (Florence, 1904), and *Pisa* (1918); V. Lusini, *Il duomo di Siena* (Siena, 1911); P. Bacci, *Dedalo* I, p. 319.

PISANO, NICCOLA (c. 1225–c. 1278), Italian sculptor and architect. Though he called himself Pisanus, from Pisa, where most of his life was spent, he was not a Pisan by birth. There are two distinct accounts of his parentage, both derived mainly from existing documents. According to one of these he is said to have been the son of "Petrus, a notary of Siena"; but this statement is very doubtful, especially as the word "Siena" or "de Senis" appears to be a conjectural addition. Another document among the archives of the Sienese cathedral calls him son of "Petrus de Apulia." Most modern writers accept the latter statement, and believe that he not only was a native of the province of Apulia in southern Italy, but also that he gained there his early instruction in the arts of sculpture and architecture. Those, on the other hand, who, with most of the oldest writers, prefer to accept the theory of Niccola's origin being Tuscan, suppose that he was a native of a small town called Apulia near Lucca.

Except through his works, little is known of the history of Niccola's life. As early as 1221 he is said to have been summoned to Naples by Frederick II to do work in the new Castel del l'Uovo. This fact supports the theory of his southern origin, though not perhaps very strongly, since, some years before, the Pisan Bonannus had been chosen by the Norman king as the sculptor to cast one of the bronze doors for Monreale cathedral, where it still exists.

In 1259 as an incised inscription records, he finished the marble pulpit for the Pisan baptistery; this is his most important early

work, and is entirely classical in spirit.

It is a high hexagon, on semicircular arches, with trefoil cusps, supported by seven marble columns, three of which rest on white marble lions. In design it presents a combination of Gothic forms with classical details. Five of the sides of the main hexagon have panels with subjects—the Nativity, the Adoration of the Magi, the Presentation in the Temple, the Crucifixion and the Last Judgment. These are all works of the highest beauty, and a wonderful advance on anything of the sort that had been produced by Niccola's predecessors. The drapery is gracefully arranged in broad simple folds; the heads are full of the most noble dignity; and the stately beauty of the Madonna could hardly be surpassed. The panel with the Adoration of the Magi is perhaps the one in which Niccola's study of the antique is most apparent. The veiled and diademed figure of the Virgin Mother, seated on a throne, recalls the Roman Juno; the head of Joseph behind her might be that of Vulcan; while the youthful beauty of an Apollo and the mature dignity of a Jupiter are suggested by the standing and kneeling figures of the Magi.

The beautiful relief of the Deposition from the Cross in the tympanum over a side door at San Martino at Lucca was probably Niccola's most important work. Then followed the Arca di San Domenico, in the church at Bologna consecrated to that saint. This work was completed in 1267 in collaboration with the Dominican Fra Guglielmo. The most magnificent of Niccola's works is the great pulpit in Siena cathedral. It is much larger than that at Pisa, being an octagon on cusped arches and columns. The contract for this work (1266) discloses the names of Niccola's assistants: Arnolfo (di Cambio) Donato, and Lapo—besides his son Giovanni. In the reliefs of this pulpit can be traced the influence of the great Gothic sculptors of France. They mark the beginning of a new epoch in the history of Italian sculpture; classical repose is sacrificed for expression of religious emotions.

Niccola's last great work of sculpture was the fountain in the piazza opposite the west end of the cathedral at Perugia. This is a series of three basins rising one above another, each with sculptured decoration; it was begun in 1274 and completed, with the co-operation of Niccola's son Giovanni, and of Arnolfo di Cambio. Niccola appears also to have had knowledge of architecture, for, when he signed the contract for the pulpit in Siena, he stipulated that he might go to Pisa four times a year to attend consultations about the building of the cathedral and baptistery. Many important buildings are ascribed to him by Vasari without corroboration. In 1278 Niccola is mentioned for the last time as working on the fountain in Perugia. The first record of his death occurs in Sienese archives under the date Aug. 30, 1287.

Though Niccola's importance as a reviver of the old traditions of beauty in art has been to some extent exaggerated by Vasari, yet it is probable that he, more than any other man, was the means of starting that new birth of the plastic arts which, in the years following his death, was so fertile in countless works of the most unrivalled beauty. Both Niccola and his son had many pupils of great artistic power, and these carried the influence of the Pisani throughout Tuscany and northern Italy, so that the whole art of the succeeding generations may be said to have owed much of its rapid development to this one family.

See SCULPTURE, and general histories of Italian art; John Symonds, *Renaissance in Italy* (1875–86); K. Frey, Vasari I (1911, 1909, p. 423); I. Supino, *Arte Pisana* (Florence, 1904); M. Reymond, *La Sculpture florentine I* (Florence, 1897); A. Brach, *Nicola and Giovanni Pisano* (Strassburg, 1904).

PISANO, VITTORE (1397–1455), commonly called PISANELLO, Italian medallist and painter, was the son of a Pisan father called Bartolommeo and a Veronese mother. He was one of the leading artists of his age, and enjoyed great celebrity during his lifetime. Guarino, a distinguished humanist, sings his praises in lines such as these: "Great is the renown that comes to Verona from the excellence of your work," and "Our age has produced you to be numbered with the great sculptors and painters of antiquity." We know nothing concerning Pisanello's artistic education. Vasari, who likes to derive all great art from Florence, states that he studied under Andrea del Castagno in Florence. But he was more probably trained in Verona in the traditions of Alti-

chiero. About 1422 he worked in conjunction with Gentile Fabriano in the great council hall of the doge's palace in Venice. During their stay in Venice the two artists exercised a great influence on the development of Venetian art. Pisanello was much favoured by the princes and potentates of Italy. There is evidence that he worked at various times at Ferrara, Mantua, Milan, Pavia, Naples, Rome, Venice and Verona. He was well received at the courts of his patrons; he designed their costumes, the patterns of the material they used, the harness for their horses, besides painting their portraits and Madonna pictures.

Unfortunately, only very few of his paintings have survived. These are: the fresco of "The Annunciation" in S. Fermo at Verona and the fresco painted on the arch of the Pellegrini chapel in S. Anastasia, in the same city, representing "St. George Mounting His Horse"; three easel pictures may be singled out as representative of the master; the "Miraculous Stag Appearing to St. Eustace" in the National gallery, London; the portrait of a princess of the house of Este in the Louvre; and the portrait at the gallery in Bergamo of Lionello d'Este, who was one of the artist's chief patrons and admirers. These panels are carefully finished to the minutest detail, and are beautifully drawn. The Louvre possesses in the Vallardi book a number of delicate and spirited pen drawings by Pisanello. These detailed studies of nature, in which animals figure very largely, seem to have been his great delight and display the powers of an extraordinary draftsman. But it is for his medals and plaques that Pisanello is best known. Although he was not, as was at one time asserted, the inventor of the medal, it was he who initiated this form of art as one of the most characteristic productions of the Renaissance. Pisanello's earliest medal was probably that of the Greek emperor John VII Paleologos, dated about 1438-39.

See Alois Heiss, *Les Médailles de la Renaissance* (1881); G. F. Hill, *Pisanello* (1905); J. de Foville, *Pisanello et les médailleurs Italiens* (1908); G. Biadego, *Pisanus Pictor* (Venice, 1908); *Les Dessins de Pisanello et de son école conservés au Louvre* (1911-20). (I. A. R.)

PISAURUM (mod. Pesaro, *q.v.*), an ancient town of Umbria on the Via Flaminia, 26 mi. from Ariminum and 8 from Fanum Fortunae. A Roman colony was founded there in 184 B.C., at the mouth of the river Pisaurus (mod. Foglia; the sea has since receded about half a mile). It was destroyed by the Goths in 539, and restored by Belisarius in 545.

PISCES, the Fishes, in astronomy, the 12th sign of the zodiac, represented by 2 fishes tied together by their tails, and denoted by the symbol X . In Greek legend Aphrodite and Eros, while on the banks of the Euphrates, were surprised by Typhon, and sought safety by jumping into the water, where they were changed into two fishes. This fable, however, as in many other similar cases, is probably nothing more than an adaptation of an older Egyptian tale. The constellation contains only faint stars without any striking grouping. *Piscis australis* or *austrius*, the southern fish, is a constellation of the southern hemisphere. It contains Fomalhaut, a star of the first magnitude, which is located at a distance of around 24 light-years from the sun. It is thus one of the sun's nearer neighbours. *Piscis volans*, the flying fish, is a southern constellation introduced by John Bayer in 1603. The name is now abbreviated to *Volans*.

PISCICULTURE. The species of food fish that can be kept successfully in ponds throughout their lives from egg to adult are exceedingly limited in number. The various breeds of goldfish and minnows (*Cyprinodonts*) are familiar examples and the carp is an example of food fishes capable of similar domestication. In the United States trout, sunfishes and the black bass are almost as fully domesticated. Various other food fishes, both marine and fresh-water, can be kept in ponds for longer or shorter periods, but refuse to breed, while in other cases the fry obtained from captive breeders will not develop. Consequently there are two main types of pisciculture: (1) the rearing in confinement to a mature stage of the young of domesticated breeders; (2) the stocking of natural waters with eggs or fry from captured or domesticated adults.

Fish-rearing.—Of the first type of pisciculture there are several examples of commercial importance in the cultivation of

fresh-water fishes. The pond culture of carp is important in China and Germany, but in England it has long fallen out of use and is not likely to be resumed so long as other fresh fish can be obtained and distributed as readily as is now the case. In the United States pond culture of carp has been practically discontinued because of the prejudice of native Americans against the fish and because of its great increase in natural waters which now afford a large commercial yield. In central Europe, on the other hand, intensive methods have been applied to pond culture with remarkable results in recent years.

In the United States some species of trout and charr have become so thoroughly domesticated that many commercial trout hatcheries have been established, some of them with scores of ponds heavily stocked with eastern brook trout (*Salvelinus fontinalis*), as well as other species, sorted into different ponds according to size and fed usually on slaughterhouse offal in addition to such natural food as they may obtain. Under this system the trout grow much faster than the wild ones, a growth of from 7 to 11 in. during the first year being no exception. Many of the fish are killed and sold before they are sexually mature; but some are kept until they reach sexual maturity in the second or third fall of their life and are then stripped and sold immediately thereafter. The ova have a high market value for sale to other hatcheries.

Next in order of importance are the North American basses and sunfishes (family Centrarchidae), all of which make "nests." The most important members of the family are the largemouth (*Aplites salmoides*) and smallmouth (*Micropterus dolomieu*) black bass which are propagated in large numbers of state, national and private hatcheries and ponds. Artificial nest boxes with bottoms covered with material suitable for the species are sometimes placed in the ponds, the fish spawn in them and the male guards the nests and schools of fry. The schools of young, usually numbering several thousand to the nest, are transferred to rearing ponds and fed on *Daphnia* raised in small separate ponds and on other food. Growth of natural foods is promoted by fertilizing the ponds. Young bass are usually planted as fingerlings, 3 or 4 in. long or as yearlings. They could be raised for the market, but the cost would be prohibitive. In addition to the bass seven species of sunfishes are cultivated in the United States by similar, but simpler methods.

In the lagoons of the Adriatic and the salt marshes of various parts of France examples of the cultivation of salt-water fish are to be found analogous to the pond culture of fresh waters. There, as in ancient Greece and Rome, it is the practice to admit young fish from the sea by sluices into artificial enclosures or "viviers" and to keep them there until they are large enough to be used. An interesting modification of this method of cultivation has been introduced into Denmark. The entrances to the inner lagoons of the Limfjord are naturally blocked against the immigration of flatfish by dense growths of sea grass (*Zostera*) although the outer lagoons are annually invaded by large numbers of small plaice from the North sea. The fishermen of the district consequently combined to defray the expenses of transplanting large numbers of small plaice from the outer waters to the inner lagoons, where they were found to thrive far better than in their natural habitat.

As a result of the international North sea fishery investigations, it has been proposed to apply the same principle for the development of the deep-sea fishery in the neighbourhood of the Dogger bank. Experiments with labelled plaice, carried out in 1904 by the Marine Biological association, showed that small plaice transplanted to the Dogger bank in spring grew three or four times as rapidly as those on the inshore grounds, and the same result, with insignificant variations, has been obtained by similar experiments in later years. (See *Reports* of the ministry of agriculture and fisheries cited at the end.) In this case the deep water round the Dogger bank acts as a barrier to the emigration of the small plaice from the shores. It has consequently been proposed that the small plaice should be transported in millions to the bank by well vessels every spring.

In the United States, some species of fresh-water fishes are

seined from temporary landlocked pools created by freshets and are transferred to permanent natural waters. This is more of a salvage than a fish cultural activity.

In Europe, Japan and the United States the methods of oyster and mussel culture are similar in principle to those just described. A breeding stock is maintained to supply the beds or the "collectors" with spat, and the latter, when sufficiently grown, is then transplanted to the most favourable feeding grounds, care being taken to avoid the local overcrowding which is so commonly observed among shellfish under natural conditions.

Fish-hatching.—The second and more familiar type of pisciculture is that known as fish-hatching, with which must be associated the various methods of artificial propagation. Fertilization of the spawn is easily effected by "stripping" the eggs from the female into a moistened pan and immediately adding the milt of the male by the same process (the dry or Russian method). Water is next repeatedly added and poured off to wash the milt from the eggs, which soon swell and harden so that they may be transferred to the hatching apparatus without injury. Although simple floating hatching boxes may often be used in natural waters, for large-scale operations hatcheries are constructed and the type of apparatus employed in them depends on the eggs to be hatched. For the smaller and lighter semibuoyant or demersal eggs, such as those of whitefish (*Coregonus*), shad (*Alosa sapidissima*), etc., tall glass jars are used provided with a central inlet pipe through which water reaches the bottom of the jar and flows upward through the eggs to escape at the top. The dead eggs float and are removed by siphoning. The jars are grouped into "batteries," each of which may be merely a number of jars set on a table and supplied with water from a pipe above them, as in hatching shad. For hatching whitefish and pike perch eggs a battery may consist of more than 200 jars arranged in four superimposed tiers on two sides of a complicated system of wooden troughs, which serve to convey water to and from them.

For hatching the larger and heavier demersal eggs of trout and salmon primitive apparatus, still in use in parts of Europe, consists of long wooden troughs in which the eggs lie on gravel in running water. In more modern hatcheries, in order to economize space and utilize the water supply to the best advantage, the troughs are divided into "boxes" by transverse partitions and the boxes are filled with trays or baskets of eggs. The partitions are so constructed that the water which flows along the trough from box to box is given an upward or downward movement through the eggs in each box. For hatching trout eggs ten shallow wooden trays with bottoms of wire gauze each supporting a single layer of eggs are stacked in each box, covered by an empty tray and latched down by a crossbar. A trough of 5 boxes carries from 500,000 to 750,000 eggs. The trout fry remain on the trays until a week or ten days before the yolk sac is absorbed and are then planted or transferred to rearing ponds. Four Pacific salmon baskets of wire screen are half filled with eggs (about 30,000), and one basket is placed in each box with the top projecting above the water so that no eggs can escape. The newly hatched fry fall through the meshes in the bottom of the basket and remain on the bottom of the box until the heavy yolk is so far absorbed that they are able to swim upward. They may be then planted or held and fed in artificial ponds near the hatcheries to be planted when a year or more old.

For the buoyant eggs of cod, use is commonly made of the McDonald or tidal hatching box which is so constructed that a jet of water gives a rotary motion to the eggs while an intermittent siphon causes the water in the box to rise and fall at regular intervals, so that the rotating eggs are carried up and down much as they would be by the waves of the open sea.

The hatching of the eggs, whether of fresh or salt-water fishes presents no serious difficulties, if suitable apparatus is employed; but the rearing of fry to an advanced stage, without serious losses, is less easy, and in the case of sea fishes, with pelagic eggs, the larvae of which are exceedingly small and tender, is still an unsolved problem, although recent work carried out at the Plymouth laboratory of the Marine Biological association, in England, is at least promising. It has been found possible to

grow pure cultures of various diatoms, and by feeding these to various larvae kept in sterilized sea water, great successes have been attained. In fresh-water culture there may be little advantage in artificial hatching, unless it is followed by a successful period of rearing. Thus, the Howieton Fishery company (England) recommended their customers to stock their streams either with unhatched ova sown in redds or with three-months-old fry. Their experience is "that there is no half-way house between ova sown in redds and three-months-old fry. Younger fry may do, but only when ova would do as well and at half the cost."

In marine hatcheries, on the other hand, it is the invariable practice to hatch the eggs, although the fry have to be put into the sea at the most critical period of their lives, in an environment which teems with predacious enemies. Current thinking is unfavourable to artificial propagation of most marine fishes because the numbers which can be handled in hatcheries are insignificant in comparison with the natural spawning potential. Protection of the stocks by regulation of the fishery is considered more effective and economical.

Some of the investigations made in the United States in recent years in the cultivation of fish and shellfish are shown by the examples which follow. They suggest the importance of a detailed knowledge of the life history of the forms to be cultivated and the advantages of rearing to a suitable stage.

Decline in the Pacific salmon fishery led to the establishment of hatcheries until in 1921 there were 90 such establishments maintained by the United States, by the individual states and by British Columbia. But in spite of the great hatchery output, the fishery continued to decline alarmingly in certain localities. This apparent failure of the hatcheries to rehabilitate the fisheries led the authorities of the United States and British Columbia to promote a co-operative and detailed study of the life history of the Pacific salmon in the hope that this would reveal better means of artificial propagation or enable fisheries restrictions to be intelligently applied. In 1924, by act of congress, full control of the Alaskan fisheries was placed in the hands of the department of commerce and has since been exercised by its bureau of fisheries and fish and wildlife service of the department of the interior.

There are five species of Pacific salmon (*Oncorhynchus*), all of which ascend from the sea into the rivers to spawn and are captured in commercial nets on the upward journey. Unlike the Atlantic salmon, they invariably die after spawning, but the young hatched from their eggs return to the sea after a longer or shorter stay in fresh water. Investigations of the past 20 years have added many important details of the life history. The method of investigation consists, in part, in marking the young by removal of some of the fins, releasing them in fresh water at various ages and in various places and recovering the marked fish when they return from the sea to fresh water to spawn. In part it consists of the microscopic study of the markings of the scales of returning adults. From these the age, rate of growth and period of time spent in fresh water may be determined. From these investigations it is now known that the fry may begin their return to the sea soon after hatching (pink and chum salmon), or may remain in fresh water for a year (silver salmon) or from 1 to 4 years (red salmon) or, as in the chinook, they may either start for the sea soon after hatching or when 12 or 18 months old. The age at return to fresh water also varies. In the pink it is invariably two years, in the chum from two to five or six years, in the silver three years, in the red three to seven years, in the chinook two to seven or eight years.

The salmon of each species almost invariably come back to spawn in the stream or lake in which they were hatched (parent stream). This "parent stream theory" with the resultant conception of each species as made up of numerous self-contained colonies or races of interbreeding individuals is most important. It results that if commercial fishing or other obstruction of a stream prevents so many individuals of any race from returning to their home spawning ground that an adequate breeding stock is not maintained, that race is depleted or disappears and its racial ground is not afterward colonized by other races. It is then

essential that commercial fishing be so conducted as to permit the escapement to the spawning ground of enough breeding fish of each colony to maintain that colony. In Alaska, the U.S. fish and wildlife service now requires a "spawning escapement" of 50%. How large the spawning escapement must be to maintain a racial population in any locality is not yet definitely known. Actual counts made under the direction of Dr. C. H. Gilbert have shown that in the Karluk river, Alaska, three red salmon returned in 1926 for each parent fish of the 1921 spawning escapement. This ratio does not include the fish of the 1921 hatch that returned in earlier years or those still to return. If the proportion should prove to hold for all seasons an escapement of less than one-third would serve to maintain the race. It has more recently been determined that the natural mortality of the young salmon, both in the streams and at sea, has a tremendous influence on the size of the runs. Consequently, the actual desirable ratio of escapement may be variable, depending upon survival. A low escapement with favourable survival may produce better returns than a higher escapement followed by conditions adverse to hatching and growth of young.

From studies made on the return of young salmon marked and released in fresh water, evidence is accumulating that artificial propagation may be made effective in offsetting the effects of artificial obstructions such as large dams. It has been found that marked fingerlings of the Alaskan sockeye or red salmon, released in the Columbia river in the fall of their first year, fail to return, but if released in the spring of their second year, they return; success does not necessarily depend merely on the release of great numbers of large and vigorous fingerlings, but on their release at the right age, the age at which they naturally begin their seaward voyage. A massive experiment on the Columbia river has demonstrated that runs may be relocated in different tributaries by proper rearing and release of fingerlings. However, where streams are unaffected by artificial structures, pollution or excessive silt loads, as in Alaska and parts of British Columbia, present policy is to curtail hatchery operations and depend upon natural reproduction.

A classic example is the rehabilitation of the Frazer river run in Canada now being undertaken by an international commission. The major policy involves the removal of obstacles and the opening and improvement of natural spawning areas, rather than extensive resort to artificial propagation. However, where man has changed the character of the river system, hatcheries may be a principal tool in maintaining runs of salmon.

In the United States many of the natural oyster beds have been so exploited that they have disappeared and others are greatly depleted. The great size of the beds, the high cost of labour and the relatively low price of the product make the method of pond culture currently employed in France and Japan impracticable. Culture consists at present wholly of rehabilitating the beds in natural waters and increasing their number (planted beds). About half the 30,000,000 bu. of oysters marketed annually are now obtained from planted beds and in the New England states about 90% are from that source.

In the United States experiments looking toward the artificial rearing of larvae of oysters and of fresh-water mussels, from which pearl buttons are made, were undertaken. While these experiments were successful in the laboratory, the procedures developed have not been put into actual practice.

In the lobster (*Homarus*) the eggs are carried attached to the appendages of the lower surface of the abdomen of the female and average 30,000 in lobsters 13 in. long. The larvae hatched from the eggs pass through a remarkable series of transformations at successive moults. During the first four stages they are minute and free-swimming and subject to destruction by storms and countless enemies; but at the close of the fourth stage, or in the fifth, they become ambulatory, descend to the bottom and show an ability to protect themselves. "One lobster at this stage is worth many thousands in the first" (F. H. Herrick). Because of the hard outer shell it is not possible to "strip" the lobster; and cultivation, therefore, consists in rearing the naturally hatched young through the helpless free-swimming stages to the ambula-

tory bottom stage capable of self-protection. One early method was that devised by A. D. Mead and his co-workers and first used at Wickford, R.I., under the auspices of the Rhode Island commissioners of inland fisheries. This method, involving the use of floating wooden boxes, with paddle wheel to provide water circulation, was never generally adopted. Its principles were applied to more conventional hatcheries, and several establishments now rear hundreds of thousands of fourth-stage lobsters in apparatus similar to that used in hatching cod eggs.

Objects and Utility of Fish-Hatcheries.—The earlier advocates of artificial propagation and fish-hatching seem to have been under the impression that the thousands of fry resulting from a single act of artificial propagation meant a corresponding increase in the numbers of edible fish when once they had been deposited in suitable waters; and also that artificial fertilization ensured a greater proportion of fertilized eggs than the natural process. For the first proposition there is no evidence, while the second proposition is now discredited. The advantage of artificial hatching lies in protecting the unhatched eggs from the very large destruction to which they are subjected under natural conditions. But it is recognized that the great fertility of fishes is nature's provision to meet a high mortality—greater in sea fishes with minute pelagic eggs—a condition which entails a greater delicacy of their larvae at the time of hatching. Artificially propagated eggs and fry must submit, *after planting*, to the same mortality as the other eggs and fry around them. Consequently, it is useless to plant out eggs or fry unless in numbers sufficiently great to increase appreciably the stock of eggs and fry of the same age already existing. It is this, combined always with the suitability of the external conditions, which accounts for the success of the best-known experiments of U.S. pisciculturists.

The shad fisheries of the streams of the east coast of the United States declined on the whole 74% from 1896 to 1923 and are now totally destroyed in many streams, in spite of plants of fry which reached the large total of 400,000,000 in 1898. We have still little knowledge of the habits and life history of the shad, of the extent and direction of its migrations. Its ascent of streams has been often impeded by dams, and pollution has doubtless adversely affected the spawning migration, vitiated the breeding grounds and destroyed the fry. Artificial hatching has failed to maintain the species in Atlantic waters under these handicaps and in the face of intensive fishing. Under more normal physical conditions and with fuller knowledge of the life history of the species it might be effective in these waters as it begins to be in the case of the Pacific salmon. The artificially propagated eggs of the shad from the eastern rivers of the United States were planted in those of California, where the species did not naturally occur. The conditions were suitable, and the species became at once acclimatized and has increased greatly. Similarly, reservoirs and streams can be stocked with various kinds of fish not previously present. But in the case of indigenous species the breeding stock must be very seriously reduced before the addition of the eggs or fry of a few score or hundreds of fish can appreciably increase it.

In the case of sea fishes it is becoming increasingly recognized that the millions of cod fry which were formerly turned out of the U.S., Newfoundland and Norwegian hatcheries were but an insignificant fraction of the billions of fry naturally produced. A single female cod liberates, according to its size, from 1,000,000-5,000,000 eggs in a single season. Yet the annual output of fry from each of these hatcheries rarely exceeds 200,000,000, *i.e.*, the natural product of a few hundred cod at most. In Britain, marine hatcheries have been established by the fishery board for Scotland in the Bay of Nigg, near Aberdeen, by the Lancashire Sea Fisheries committee at Peel and by the government of the Isle of Man at Port Erin. These establishments have been principally devoted to the hatching of the eggs of plaice. But again the maximum output of fry from any one of these establishments has not exceeded 50,000,000 in any single year. As a single female plaice produces about 200,000 eggs per annum, this output does not exceed the natural produce of a few hundred fish. Under these circumstances the probable utility of the operations could be admitted only if the fry were sedentary and could be planted

in suitable localities where young fish were naturally scarce. But the fry drift with the currents as helplessly as the eggs, and the *a priori* objections to the utility of the operations have in no case been met by satisfactory evidence of tangible results.

The Scottish fishery board carried out a large-scale experiment from 1896 to 1908 which was very illuminating (Thomas Fulton, 26th Report). They attempted to measure the density of young plaice on the beaches of Loch Fyne during six years when plaice fry were liberated in the loch and a similar period when none were added. From 1896 to 1901 the quantities of fry added were 4, 21, 19, 16, 30 and 51 millions annually, the number of eggs naturally present in the loch being estimated at nearly 500,000,000 in 1898 (Henry Williamson, 17th Report). Although the figures of young plaice on the beaches yielded an average density which was twice as great in the first period as in the second (88:40 per hour), there was little or no correspondence from year to year between the density of young fish and the number of fry planted. The highest record corresponded with the year of maximum output of fry (1901), but the next highest occurred in 1905, when no fry were planted, and the third occurred in the first year (1896), when the number planted was negligible (4,000,000). Assuming (which is not certain) that the coincidence in 1901 was significant, it nevertheless appears that the natural fluctuations in the number of young plaice were unaffected by the hatching operations except in the one year when the number of fry liberated exceeded 50,000,000 and thus formed an appreciable proportion (10%) of the number estimated to be naturally present. Even these numbers do not provide Loch Fyne with a regular plaice fishery.

In the United States the utility of the cod-hatching operations in the past has been so discredited that the work is now confined to the salvaging of mature eggs taken in commercial fishing operations. These are fertilized and planted on the fishing grounds or, occasionally, transferred to hatcheries. This is merely a salvage operation.

The situation is much the same with regard to the operations of the Newfoundland hatcheries at Dildo. (See Charles Fryer, Reports x-xii of H.M. inspectors of sea fisheries, east and west.)

The most exact investigations bearing upon this problem are those undertaken in Norway in connection with the cod-hatching operations at Arendal under Capt. Gunder Dannevig. Four fjords were selected on the south coast of Norway in proximity to the hatchery, and the usual number of fry (10,000,000-30,000,000) was planted in the spring in alternate fjords, leaving the intermediate fjords unsupplied. The relative number of young cod in the various fjords was then carefully investigated throughout the succeeding summer and autumn months. It was found that there was no relation between the abundance of young fish and the presence or absence of "artificial" fry. In 1904, 33,000,000 fry were planted in Sondelfjord and young fish were exceptionally abundant in the following autumn (3 times as abundant as in 1903, when no fry were planted). But their abundance was equally striking in other fjords in which no fry had been planted, while in 1905 all the fjords were deficient in young cod whether they had been planted with fry from the hatchery or not. (For a summary of these investigations see *Papers* on "Artificial Fish-hatching in Norway" by Captain Dannevig; and Knut Dahl, *Report of the Lancashire Sea Fisheries laboratory for 1906*, Liverpool, 1907).

It would seem clear that the attempts hitherto made to increase the supply of sea fish by artificial hatching alone have been unsuccessful. Little serious thought is now given to this method of husbanding or developing the resource. The increase of the supply of the migratory marine species, such as the cod, depends on a more complete knowledge of habits, life histories and migrations. With this knowledge in hand these fisheries may be maintained or increased either through regulation or by artificial propagation or by both means; until it is in hand the effect of artificial propagation must be considered as negligible.

In the smaller bodies of fresh water there is no doubt of the effectiveness of hatchery operations; but in the Great Lakes of North America there is no dependable evidence of their value. Official statistics studied by P. Reighard in 1908 showed, on their

face, a correlation between the average intensity of the plants of whitefish fry in certain regions of the Great Lakes during three five-year periods from 1892 to 1906 and the average catch of whitefish for the same periods. Intensive planting was found to be correlated with an increased fishery output and was recommended. On the other hand Dr. W. Koelz, who has an intimate knowledge of the fisheries operations of the Great Lakes is doubtful of the value of statistics based largely on reports of interested parties, the fishermen. He points out further that the planted fry are a very small fraction of those presumably hatched naturally (0.35% in Lake Huron in 1900). His findings are supported by later observations of John van Oosten.

The decline in the coregonine fisheries of the Great Lakes is further evidence of the inadequacy of present hatchery methods. Whether the whitefish (*Coregonus clupeaformis*) has declined is uncertain, but the bluefin of Lake Superior and the bloater of Lake Ontario (both forms of *Leucichthys nigripinnis*) have become commercially extinct and in 1925 the important Lake Erie herring (*L. artedii*) suddenly gave out and has not since regained its commercial importance. The bluefin and bloater were never propagated artificially, but hundreds of millions of Lake Erie herring eggs have been hatched annually. It appears from these three cases that, for some unknown reason, when the breeding stock of a gregarious fresh-water species has been reduced below a certain numerical minimum the decrease continues. In the case of the bloater it has led to extinction and the important Lake Erie herring, in spite of extensive hatchery operations, remain at an ebb of abundance. The value of artificial hatching as hitherto carried out in the Great Lakes is now questioned in the United States for the reasons stated above and in Canada the abolition of hatcheries has been advocated by Prof. A. P. Knight of the biological board of Canada. It is probable that the life histories and migrations of many species approach in intricacy those of the Pacific salmon with its numerous, independent, self-sustaining colonies or races. Until these intricacies are resolved by prolonged research and hatchery operations adjusted to them, it is felt that artificial propagation is, with certain exceptions, carried on blindly and that success depends on chance.

The exception which provides reasonable evidence of the adequacy of artificial propagation is the propagation of game species for stocking in the smaller fresh-water lakes and streams. In certain states a large part of the trout fishing is derived from hatchery plants. The planting of legal-sized trout demonstrably provides quarry for the angler, although the practice is somewhat expensive and artificial in its nature. Many streams have been so changed in their characteristics that trout no longer breed naturally in any numbers, but the hatchery stock does survive until it is caught out.

A recent development in the United States is a program of constructing and stocking small farm ponds. These ponds, normally ranging from ½ ac. to several acres in size, are stocked with large-mouth bass and sunfish fingerlings in a ratio of 100 bass to 1,000 or 1,500 sunfish per acre. The ponds are then fertilized to produce natural food and may yield from 200 to 300 lb. of fish per year. Tens of thousands of these ponds have been constructed since 1940, and the capacity of state and federal hatcheries is taxed to produce enough young fish to meet the demand.

The federal fish and wildlife service in 1946 operated 108 hatcheries and rearing stations, in contrast with about 130 operated 10 years earlier. Most of these are devoted to the propagation of Pacific salmon, trout and pondfishes, the latter going to supply the farm ponds with seed stock.

The various states likewise engage in these activities, with several hundred units in active operation. The objectives are similar to those which engage the federal government. In both instances the hatcheries are increasingly viewed as tools of a multiple management program which involves other factors such as improvement of environment, protection by regulation of fishing, pollution abatement and scientific research.

PISCINA, originally a fish pond; later any artificial pool or tank, such as a bathing or swimming pool. Ecclesiastically the term is used for the stone basin with a drain emptying upon virgin soil, in which the utensils of the mass are cleaned and ritual ablutions performed. In mediaeval churches, especially in England, piscineae are most frequently in the chancel, close to the altar and often set in recessed, arched niches of great beauty.

PISEK, a town of Bohemia, Czech., on the Otava, in one of the cereal and cattle basins of south Bohemia and on a main line from Prague to Budejovice, Linz and Vienna. It was occupied by Germany in 1939. Pop. (1930) 16,973.

PISEMSKY, ALEXEY TEOFI-LACTOVICH (1820-1881), Russian novelist, was born on his father's estate in the province of Kostroma, on March 22, 1820, the son of a major who had risen from the ranks. From the gymnasium of Kostroma he passed through Moscow university, and spent over 20 years in the government service. His first novel, *Boyarstchina*, was forbidden by the censor. His principal novels are *Tyufyak* ("A Muff"), 1850; *Tsytyacha Dush* ("A Thousand Souls"), 1862; and *Vzbalomuchenoe marye* ("A Troubled Sea"), giving a picture of the excited state of Russian society about the year 1862. His *Gorkaya sudbina* ("A Bitter Fate"), depicting the dark sides of the Russian peasantry, obtained for him the Ouvaroff prize. He died at Moscow on Feb. 2, 1881. Pisemsky was a realist, and took an objective view of the unrest among the intelligentsia, which made him very unpopular in Moscow literary society. His best work is his description of the life of the common people. He learnt to know them thoroughly when investigating conditions in the Russian interior.

A PISCINA IN EXETER CATHEDRAL

PISHPEK: see FRUNZE.

PISIDIA, anciently a region of southern Asia Minor, lying to the north of Pamphylia and to the west of Isauria and Cilicia. To its west the district of Milyas was generally taken as Pisidian, but was on occasion included in Lycia, while to its north the populous and strongly Hellenized area around Pisidian Antioch was sometimes counted as Phrygian and given the name Phrygia Pisidica or Phrygia Paroreius.

Pisidia included some fertile plateaus and high valleys, such as those of the Catarrhactes and Cestrus, which were rich in olives, vines, pastures, timber, resins and iron. But most of the district was composed of the abrupt north-south trending limestone ranges of Taurus, providing refuge for a lawless population, much given to pillage, which resisted stubbornly its successive conquerors: Alexander the Great, King Amyntas of Galatia, and the Roman general Publius Sulpicius Quirinus. At the end of the republic, the population was organized in small tribes, or in groups of villages known as communes, the chief centres of which were Termessus, Sagalassus, Selge and Cremna.

According to Strabo (XIII, iv, 17) the Pisidian language was distinct from those of the nearby Solymi and Lydians. The theocratic rule so characteristic of ancient Phrygia seems to have obtained also in Pisidia, where there is evidence of temples with large estates and servile labour, the most famous being that of Men Ascaenus near Antioch.

On the death of King Amyntas in 25 B.C., the greater part of Pisidia was incorporated in the newly constituted Roman province of Galatia, though it was partly regrouped with Lycia and Pamphylia by Vespasian in A.D. 74. Augustus began its Romanization by founding military colonies, first at Antioch (Colonia Caesarea) and later at Cremna, Comama, Olbasa, Parlais and Lystra. In addition, the Via Sebaste was built forward in two directions from Antioch: one branch joining the highway from Laodiceia to Pamphylia at Comama, and the other running to Iconium and Lystra. The advance of Roman civilization was at first slow, and very little coinage was struck in Pisidia in early imperial times, but in the 2nd century A.D. urbanization proceeded apace, and baths, markets, gymnasiums, temples and porticoes were built even in the little towns of the Milyades. In the following century, however, the Pisidian cities, like those of many other parts of Asia Minor, suffered a serious decline.

On the reorganization of the empire by Diocletian about A.D. 297, Pisidia was included in the Dioecesis Asiana, and in later Byzantine times it fell partly in the Thracian and partly in the Anatolic theme (province).

PISO, the name of a distinguished Roman plebeian family of the Calpurnian gens which continued in existence till the end of the 2nd century A.D. Nearly 50 of its members were prominent in Roman history, but the following deserve mention.

1. **LUCIUS CALPURNIUS PISO CAESONINUS**, Roman statesman, was the father-in-law of Julius Caesar. In 58 B.C., when consul, he and his colleague Aulus Gabinius entered into a compact with P. Clodius, with the object of getting Cicero out of the way. Piso's reward was the province of Macedonia, which he administered from 57 to the beginning of 55, when he was recalled, perhaps in consequence of the violent attack made upon him by Cicero in the senate in his speech *De provinciis consularibus*. On his return Piso addressed the senate in his defense, and Cicero replied with the speech *In Pisonem*. Piso issued a pamphlet by way of rejoinder, and there the matter dropped, Cicero being afraid to bring the father-in-law of Caesar to trial. At the outbreak of the civil war Piso offered his services as mediator, but when Caesar marched upon Rome he left the city by way of protest.

Piso did not, however, definitely declare for Pompey, but

remained neutral. After the murder of Caesar he insisted on the provisions of his will being carried out, and for a time opposed Antony. Subsequently he became one of his supporters, and is mentioned as taking part in an embassy to Antony's camp at Mutina.

2. **LUCIUS CALPURNIUS PISO**, surnamed *Frugi* (the worthy), Roman statesman and historian, was tribune in 149 B.C. He is known chiefly for his *lex Calpurnia repetundarum*, which started the system of establishing regular courts for the trial of particular offences in place of the old system of special tribunals being appointed for each case. As praetor (136) and consul (133) Piso fought against the slaves in Sicily.

See ANNALISTS; C. Cichorius in Pauly-Wissowa's *Realencyclopädie* (1897), vol. iii., pt. 1; H. Peter, *Historicum romanorum reliquiae* (1870), vol. i.; Teuffel-Schwabe, *Hist. of Roman Lit.* (Eng. trans.), § 132, 4. On the *lex Calpurnia*, *Corpus inscr. latinarum*, i., No. 108, with Mommsen's commentary; A. H. J. Greenidge, *Hist. of Rome*, 133-104 B.C. (1904).

3. **GNAEUS CALPURNIUS PISO**, Roman statesman, was consul in 7 B.C. and subsequently governor of Spain and proconsul of Africa. In A.D. 17 Tiberius appointed him governor of Syria, with secret instructions to thwart Germanicus, to whom the eastern provinces had been assigned. The indignation of the people at the death of Germanicus, and the suspicion that Piso had poisoned him, forced Tiberius to order an investigation. Piso committed suicide, though it was rumoured that Tiberius, fearing incriminating disclosures, had put him to death.

See H. Schiller, *Geschichte der römischen Kaiserzeit* (1883), vol. i.

PISSARRO, CAMILLE (1831-1903), French painter, was born at St. Thomas in the Danish Antilles, of Jewish parents of Spanish extraction. He went to Paris at the age of twenty, and, as a pupil of Corot, came into close touch with the Barbizon masters. Though at first he devoted himself to subjects of the kind associated with the name of Millet, his interest was entirely absorbed by the landscape, and not by the figures. He fell under the spell of the rising impressionist movement, and threw in his lot with Monet and his friends. Like Monet, he made sunlight, and the effect of sunlight on the objects of nature, the chief subjects of his paintings, whether in the country or on the Paris boulevards. About 1885 he took up the method of the pointillists, but after a few years of these experiments he returned to a broader manner. In the closing years of his life he produced some of his finest paintings, in which he set down with admirable truth the peculiar atmosphere and colour and teeming life of the boulevards, streets and bridges of Paris and Rouen. He died in Paris in 1903. Pissarro is represented in the Caillebotte room at the Luxembourg, and in most collections of impressionist paintings. Many of his finest works are in M. Durand-Ruel's collection in Paris.

PISTACHIONUT, the common name for the fruit of *Pistacia vera*, a deciduous, dioecious, sub-tropical, dry-land tree which produces much prized nuts extensively used as food and as colouring material in confections. It is believed to have originated in Syria; it is generally cultivated in the Mediterranean region and to experimental extent in both California and Oregon. The tree has broad-spreading branches but rarely attains as much as 30 ft. in height. It has 1 to 5 pairs of thick, wide, leathery, pinnate leaves and its small fruits form in clusters. The nuts are from one-half to three-fourths of an inch long, bony white and much inclined to split open at one edge, without discharging the kernel. Each nut is encased within a thin, tightly adhering, wrinkled and reddish skin. The kernels are single, solid pieces, with pleasing mild flavour. The principal varieties under cultivation are Aintab, Alemi, Ashoori, Bronte, Buenze, Koz, Minassian, Red Aleppo, Sfax, Sicilian, and Trabonella. These are interplanted at the rate of about 1 to 20 with Kaz and Peters used as pollinizers. During the 5-year period ending June 30, 1941, the United States imported an average of 3,270,400 lb., of which more than 40% were from Syria. A close relative, *P. chinensis*, the Chinese pistache, is much prized because of the autumnal beauty of its foliage. (C. A. Rd.)

PISTOIA or **PISTOJA**, a town and episcopal see of Tuscany, Italy, capital of the province of Pistoia, 21 mi. N.W. of

Florence. Pop. (1936) 29,532 (town); 72,212 (commune). It is situated on a slight eminence (210 ft.) near the Ombrone, one of the tributaries of the Arno, immediately below the Apennines. It is on the site of the Roman *Pistoriae*, near which in 62 B.C. Catiline was slain and his forces destroyed. Excavations in the Piazza del Duomo led to the discovery of a large private house (end of 1st century B.C.). During the middle ages Pistoia was the scene of constant conflicts between the Guelphs and Ghibellines; here the great struggle took place which resulted in the creation of the Bianchi and Neri factions (Dante, *Inferno*, xxiv. 121). In 1302-06 it was besieged and eventually taken by the armies of Florence and Lucca, and in 1325 it became subject to Castruccio of Lucca. In 1351 it was obliged to surrender to Florence, and thenceforth shared its fate.

The city is still surrounded by walls, dating from shortly after the siege of 1302-06; while two inner lines of streets represent two earlier and inner lines of wall. A number of skilful artists between 1287 and 1399, made the great silver altar and frontal of the cathedral now in a chapel on the south side. The cathedral (13th century) has a campanile (218 ft. high) porch and façade with small arcades in black and white marble in the Pisan style as in other churches of Pistoia. It contains many fine sculptures—the monument of Cino da Pistoia, lawyer and poet, Dante's contemporary (1337), by Cellino di Nese, surrounded by his scholars, and Verrocchio's monument to Cardinal Forteguerri (1474). The octagonal baptistery is by Cellino (c. 1337). Among the earlier churches the principal is Sant' Andrea (1166), enriched with sculpture; in the nave is Giovanni Pisano's magnificent pulpit, imitated from his father's pulpit at Pisa. Other churches are S. Giovanni Fuorcivitas (so called because it was outside the line of the earliest, pentagonal, enceinte of the middle ages), with one of the long sides elaborately adorned with small arcades in the Pisan style, in black and white marble, also with sculpture by Guarnon (1162) on the façade. Within are a beautiful group of the Visitation by Andrea della Robbia, and a fine pulpit by Fra Guglielmo of Pisa (1270). S. Bartolomeo in Pantano and S. Pietro Maggiore closely resemble it. San Francesco al Prato is a fine church of the end of the 13th century with interesting frescoes of the school of Giotto. San Domenico, a noble church, begun in 1294, contains the beautiful tomb of Filippo Lazari by Bernardo and Antonio Rossellino (1462-67) and other works of art. The Madonna dell' Umiltà (1494-1567) and S. Maria delle Grazie have fine Renaissance interiors, by the local architect Ventura Vitoni. The Palazzo del Comune and the Palazzo Pretorio, once the residence of the podestà, are both fine specimens of 14th-century architecture. The Ospedale del Ceppo has remarkable reliefs in enamelled and coloured terra-cotta on its exterior. Besides various medallions, there is a frieze of figures in high relief along the whole front—groups representing the Seven Works of Mercy—executed by Andrea Della Robbia between 1514 and 1525.

The word "pistol" is derived (apparently through *pistolese*, a dagger—dagger and pistol being both small arms) from Pistoia, where that weapon was largely manufactured in the middle ages.

PISTOIA, SYNOD OF, a diocesan synod held in 1786 under the presidency of Scipione de' Ricci (1741-1810), bishop of Pistoia, and the patronage of Leopold, grand-duke of Tuscany, with a view to preparing the ground for a national council and a reform of the Tuscan Church. The synod was attended by 233 benefited secular and 13 regular priests, and decided with practical unanimity on a series of decrees which, had it been possible to carry them into effect, would have involved a drastic reform of the Church on the lines advocated by "Febronius" (see FEBRONIANISM). The decrees were issued with a pastoral letter of Bishop de' Ricci (see SACRED HEART), and were warmly approved by the grand-duke, at whose instance a national synod of the Tuscan bishops met at Florence on the 23rd of April 1787. The temper of this assembly was, however, wholly different. The bishops refused to allow a voice to any not of their own order, and in the end the decrees of Pistoia were supported by a minority of only three. They were finally condemned at Rome by the bull *Auctorem fidei* of the 28th of August 1794.

BIBLIOGRAPHY.—De' Ricci's own memoirs, *Memorie di Scipione de' Ricci, vescovo di Prato e Pistoia*, edited by Antonio Galli, were published at Florence in 2 vols. in 1865. Besides this, his letters to Antonio Marini were published by Cesare Guasti at Prato in 1857; these were promptly put on the Index. See also De Potter, *Vie de Scipion de' Ricci* (3 vols., Brussels, 1825), based on a ms. life and a ms. account of the synod placed on the Index in 1823. There are many documents in Zobi, *Storia civile della Toscana*, vols. ii. and iii. (Florence, 1856). The acts of the synod of Pistoia were published in Italian and Latin at Pavia in 1788.

PISTOL, a small firearm designed for one-hand use, dating from the early 15th century. Tradition ascribes the derivation of the word to two distinct sources, viz., (1) *Pistoia*, a city in Italy where some claim the weapon originated; and (2) *Pistole*, an ancient coin to the diameter of which it is said the earliest handguns were bored. (Yet another explanation of its origin is that it derives from "pistallo"—meaning *pommel*—the common location of the weapon for mounted troops over centuries of use.)

The advantages of a firearm which could be operated by one hand, leaving the other free for the use of an additional weapon, or for defence, must have been apparent from the earliest days of gunpowder, whence it becomes reasonably certain that the pistol evolved simultaneously with its heavier counterpart—the shoulder weapon. Indeed the most primitive form of small firearm, the "hand cannon," was more a pistol than a musket, but cannot correctly be placed in the former classification since it required one hand to hold it and another to ignite its powder charge. But with the development of the matchlock (c. 1425) it became possible to produce a light and serviceable one-hand piece, and thenceforward the history of the pistol parallels quite closely that of the corresponding shoulder-arm of the period. (See **SMALL ARMS, THE DEVELOPMENT OF.**)

Through the centuries, the pistol has received the attention of untold thousands of inventors. To render it capable of firing more than once without reloading, it has been produced in every conceivable form—as with two, three, four and more barrels—the number limited only by the weight involved, and with countless other devices incorporated. Revolving types are as old as firearms, though the earlier varieties did not embody, as does the revolver of today, a short, many-chambered cylinder positioned behind a single barrel in such manner that the charge in each chamber is brought successively in alignment with the barrel. Instead they were mere sheaves or bundles of tubes of equal length, and were revolved *by hand*, rather than mechanically as in later specimens. (The latter, in the mid-19th century, acquired the popular designation "pepper-box"—because of the resemblance of the multi-chambered muzzle to a pepper-shaker.) Nevertheless, the true revolver principle (in which cocking the hammer causes simultaneous rotation of the cylinder) is far older than is generally realized, and Samuel Colt (U.S.A.), no matter how much

some of the first-named dating from the 15th century, the last, carrying right into the twentieth. The majority of these have been more curiosities than serviceable weapons, but some few have received the stamp of actual (if limited) adoption by the military, as in the case of the Elgin percussion cutlass-pistol (U.S.A., 1837).

The date of earliest employment of the pistol as a military side-arm is obscure. Pollard tells us that it was adopted by the French cavalry in 1550, and that prior to this period it was "common in Germany." George states that the matchlock pistol was unsuited for military service, and expresses the doubt that pistols were in general use by the military prior to the wheel-lock era, or in England sooner than the opening of the reign of Charles I (1625). He bases this assumption on the absence of any reference to pistols in (army) records of the reign of Queen Elizabeth (1558–1603). Thenceforward, however, the pistol held, and holds, a definite if not overly-important place among military small arms throughout the civilized world. English-speaking nations, however, were slow to appreciate the advantages of *metallic cartridge types*, and whereas France had adopted, as early as 1853 (for her naval service), a thoroughly satisfactory 12mm. pin-fire revolver, the United States fought its Civil War (1861–65) almost exclusively with percussion hand-arms, the first delivery of American-made metallic cartridge revolvers to the military taking place in 1871. (Some few had been purchased and carried by individuals in the war then terminated, and exactly 200 [Perrin make] secured in France by the Federal Government.) England also deferred until the late '60s the adoption of a metallic-cartridge weapon, although certain German states (e.g., Bavaria) had preceded her by some years.

Contrary to popular belief, facility in the use of the pistol is not readily acquired, and indeed is infinitely more difficult to gain than in the case of the rifle. Further, the shortness of a pistol barrel, as a result of which a slight twist of the wrist swings the muzzle through a large arc, plus the difficulty of ascertaining at a glance whether certain modern types of pistols are or are not loaded, have resulted in many accidents due to carelessness, and gained for the weapon, among those unfamiliar with it, a reputation for dangerousness far greater than it deserves. In addition, the discovery by the novice that he cannot hit even large targets at close range quickly convinces him that it is a hopelessly inaccurate weapon. Even among the military, its possibilities for wide usefulness as a short-range arm, both of offence and defence, are usually studiously neglected. There remains, nevertheless, an informed and insistent element of military opinion which continues to fight for its more adequate recognition—to the extent indeed of the complete replacement of the foot-soldier's bayonet with a hand firearm.

Classification.—So many types of pistols and revolvers exist that it is next to impossible to set up suitable brackets wherein to place them. Ignoring for the moment all early specimens (i.e., not handling modern metallic cartridges), there are:

(1) Revolvers, (2) Automatic pistols, (3) Other pistols. Of these the first and third are made in a variety of forms for pin-fire, rim-fire and central-fire ammunition. Automatic pistols, however, are chambered for the last two types only, having been perfected after the pin-fire cartridge was already in its decadence. Considering in turn the three basic classes above named, it is found that a revolver is a weapon embodying an element (cylinder) which revolves, whence comes its name. (By the same token, an arm containing no such component is *not* a revolver, despite the generally loose application of the term.) Within the cylinder are bored a number of chambers, disposed equidistant from each other and from the axis about which it revolves. Each chamber is designed to contain a charge (cartridge), all being successively brought in line with the barrel, mechanically locked in position, and discharged at the will of the operator (by pressure on the trigger). Revolving cylinder-rifles (i.e., revolvers in shoulder-weapon form) long enjoyed considerable popularity (especially during the percussion era), even receiving considerable military recognition, especially in the U.S.A., but apparently no new model of this type has been offered for sale since 1880–81,

PHANTOM VIEW OF COLT OFFICIAL POLICE MODEL REVOLVER

the credit due him for improvements he contributed to this type of mechanism, lacks the honour of being its inventor by close to 200 years, perhaps many more. In addition to developing multi-shot varieties, small-arms designers have managed to produce numberless combinations of the pistol with other weapons. Thus we find it incorporated with battle-axes, "holy-water sprinklers," daggers, knives, sabres, whip handles, canes, bludgeons, pocket-books, cigar cases, bicycle handle grips, flashlights, fountain pens and in every other conceivable (and inconceivable) association,

as they are not suitable save for low-power ammunition for which other, simpler and less expensive mechanisms are everywhere available. (High-power rifles with revolving magazines, as distinguished from revolving cylinders, are by no means unknown, however.) One widely-advertised disadvantage of the revolver is the inevitable escape of some portion of the propellant gases at the junction between cylinder and barrel, and various devices to make this joint more or less gas-tight (as in the Russian "Nagant" service revolver) have been attempted. The added power thus gained is never worth the complexity of the mechanism required to attain it, however, since the percentage of gas lost, save when the gap becomes truly enormous, is almost negligible. In the conventional revolver the long axis of the cylinder is directly below and parallel to the barrel, but other (obsolete) types are not unknown wherein the cylinder revolves in a horizontal plane (Allen & Cochran, U.S.A.) or a vertical one (Noel, France; Protector, U.S.A.). Revolvers may be classified according to their modes of rotating the cylinder, or of extracting the fired case into: Single-action, Double-action, Semi-automatic, Automatic-ejecting, Hand-ejecting, Rod-ejecting, etc. In the single-action arm the acts of cocking the hammer and rotating the cylinder are performed simultaneously by the manual retraction of the former, which comes to rest in a rearward position. Thereafter a squeeze on the trigger is required to cause it to fall and discharge the piece. During the percussion era this was the accepted mode of operation (as introduced by Colt, 1836), though certain excellent double-action types such as the Tranter, Webley and Adams (all British) and the Cooper, Remington and Starr (U.S.A.) also appeared. The most celebrated existent specimen of revolver produced prior to the percussion era, in which cocking and cylinder revolution take place in the manner just described, is one in the Royal United Service Museum, London. This is of the flint-lock type, and of the period of about 1650. Conventional "revolvers" of early date (and these go all the way back to the match-lock period) invariably possess cylinders which must be rotated by hand (*i.e.*, cocking and rotation are separately carried out). The finest examples of this type are flintlocks patented in 1818 by Elisha Collier, an American then living in England. Subsequent to the general adoption of the double-action revolver (1870-90), the single-action type fell in favour, though it later regained considerable popularity for target weapons and is still produced by Colt in its "Single-Action Army" model, a weapon which has enjoyed nearly 70 years of uninterrupted production. The double-action mechanism is so designed that the hammer is cocked, and the cylinder rotated, by mere rearward pressure on the trigger, the hammer then falling and discharging the piece when such pressure is continued. To the layman this appears a most suitable design, involving as it does only a single motion, but the spring resistance within the mechanism which must be overcome by finger pressure on the trigger is so considerable, and so variable at different stages in the rearward progress of that member, that none but an expert can do good shooting when firing "double-action" save at the very closest ranges. In the hands of such persons, however, its greater speed of operation (as against the single-action) makes it the weapon of choice. (Most double-action revolvers may be operated either single- or double-action, though some of the cheaper modern types and some of the better earlier ones will function only on the latter system.) In the semi-automatic revolver the mechanism is actuated, cocking the hammer and rotating the cylinder, by the energy of recoil, which drives the whole superstructure of the piece (barrel-cylinder assembly) rearward on a horizontal platform built into the lower frame, a "recoil spring," compressed during this movement, now uncoiling to force these parts back to their forward (firing) position. The outstanding example of this type is the British Webley-Fosbery arm made in .455 (less often in .38) calibre. Another with practically identical mechanism but far less well known is the .32 calibre pocket model formerly produced by the Union Fire Arms Co. of Toledo (U.S.A.). In an automatic-ejecting revolver (first popularized by Smith & Wesson, U.S.A.), the weapon commonly "breaks open" (for loading and ejecting) at a hinge located below and

forward of the cylinder and a "spider" operating in the axis of that member automatically lifts out and expels the empty cases after the joint has opened sufficiently to permit this. In hand-ejecting models the cylinder ordinarily swings to one side when released by a latch, its axis remaining parallel to that of the barrel, whereupon a rod running through it and terminating in an ejector spider is manually pushed rearward, so withdrawing

WEBLEY REVOLVER: (1) NORMAL FIRING POSITION, (2) SECOND FIRING POSITION SHOWING TRIGGER MECHANISM, (3) THIRD FIRING POSITION, (4) FOURTH FIRING POSITION

the fired cases. In the rod-ejecting type (an excellent example of which is the Colt "Single-Action Army" model already mentioned), the cylinder must be rotated, one chamber at a time, to bring the mouths of these successively opposite the tip of a long, slender rod in a housing attached to the side of the barrel, and held in its normal (forward) position by spring pressure. This rod must then manually be pressed down into the chamber, aligned with it to disengage and eject the empty fired case within, the spring then returning it to its forward position. The operation must be repeated for each chamber to be emptied. Continental practice varies somewhat from that just described (American), but in all systems of rod-ejection each chamber must be separately and individually cleared of its contained empty case.

Other categories into which revolvers may be differentiated are: hammer and hammerless (concealed hammer) types, the former being far the commoner, but the latter (all obviously with double-action mechanisms) widely used in small "pocket" models of .25, .32 and .38 calibre wherein the spur (thumb cocking-piece) of the hammer, if present, might catch in the clothing in an attempt quickly to draw the weapon. Practically all automatic pistols are, strictly speaking, semi-automatic, since in but one or two models (Mauser, Germany), and licensed copies, are they so designed as to permit more than one discharge with each pull of the trigger. But the term "automatic" has gained such wide use that it is perforce employed in this article to designate weapons properly of the semi-automatic class. These may be divided into: Gas-

operated, Straight blowback, Blow forward, Retarded blowback and Short-Recoil types. Of the first named, but one short-lived example (the "Clair," France) was ever produced. This employed the usual gas port and expansion chamber beneath the barrel, the cartridges (French service revolver type of 8mm. calibre) being fed into the mechanism through a tubular magazine in the butt of the piece. The straight blowback, numerous models of which are produced in many countries, is, as in shoulder weapons, confined to ammunition of low power and pressure (e.g., .22 rim-fire). More powerful ammunition is handled in arms of the retarded blowback type, such as the Luger (Germany), known also as "Parabellum," or built on the short-recoil system (Webley, England; Colt, U.S.A.). Examples of the much less used blow-forward action are certain early Mannlicher (Austrian) models and the Schwarzlose (Germany). (For descriptions of the modes of operation of these several mechanisms, which duplicate exactly those embodied in machine guns and semi-automatic rifles, see GUN, MACHINE.) Magazine capacity of automatic pistols varies from about six cartridges (6.35mm. calibre) to as high as twelve (some .22 rim-fire models), the average military type holding seven to ten. Most modern military automatics are clip-loaded, but some (e.g., Mauser, Germany; Steyr, Austria) are charger-loaded.

Calibres.—These vary for revolvers all the way from 5 to 15mm. bore in pin-fire types, *i.e.*, about .20 to .60 calibre; from 2mm. (4/100") to .46 calibre or more in rim-fire, and from about 5mm. to .577 calibre in central fire. The smallest sizes (2mm.) are, of course, mere curiosities, yet capable of firing tiny ball cartridges which will destroy eyesight, if no worse. Among automatic pistols, freak arms, save as produced in tiny calibres, *e.g.*, the 2mm. Kolibri, Germany, are unusual. The smallest really effective automatic, the German "Lilliput," is of 4.25mm. (about .21") calibre; the largest, the .45 Colt (U.S.A.) and the .455 Webley (England). The accuracy of the automatic, save in specimens designed for target work (rare in calibres over .22 rim-fire), is, in average hands, commonly below that of revolvers of comparable weight and size and its construction is such that, except in certain makes which possess "loading indicators" (as the Luger), it is impossible, without opening the mechanism or pressing the trigger, to determine whether or not it contains unfired cartridges. Further, unless it possesses a "magazine safety," now incorporated in all the better makes, but formerly rare or absent, it remains dangerous even after the removal of the loaded magazine. This is due to the fact that, preparatory to firing, a cartridge must

the revolver remains in favour. Among civil servants, European police employ the automatic almost exclusively, whereas in the U.S.A. the revolver is practically without competition. Military revolvers now range in calibre from 7.62mm. (Russia) to .380 and (formerly) .455 (England); automatics from 7.63 and 7.65mm. (Germany) to .45 (U.S.A.). The revolver bullet is commonly an unjacketed missile of lead, hardened perhaps with antimony,

MILITARY MODEL OF THE MAUSER

whereas that of the automatic is usually full metal cased (jacketed), unfaced bullets being subject to deformation, because of their relative softness, when passing through the mechanism of such an arm. Full-jacketed revolver bullets are not unknown, but have never gained much popularity save with law-enforcement agents whose duties may require their firing through heavy doors, automobile bodies, etc. Muzzle velocities in standard revolvers average 600-850 foot seconds, but there has been developed (by Smith & Wesson, U.S.A.) a "Magnum" type in .357 calibre with a muzzle velocity exceeding 1,500 f.s. and a muzzle energy of 800 foot lbs., thus exceeding that of the .44 calibre Winchester (U.S.A.) repeating rifle, model of 1873, to which has probably fallen more medium and large game than to any other firearm ever produced. From the standpoint of "stopping power," the .38 or .45 calibre leaden revolver bullet of moderate velocity is more efficient than the high-velocity, automatic pistol missile of small (7.63 and 7.65mm.) bore as fired by the Mauser and Luger military automatics. For although the latter may exhibit considerably more "calculated" energy on paper, its metal case causes it to penetrate cleanly and its limited diameter results in an almost tiny perforation through the tissues, with little bleeding; and by reason of its high velocity it usually passes on through the target to expend most of its energy upon the scenery beyond. Per contra, the soft lead revolver projectile tends to "mushroom" (expand) on striking bone or other resistant body structure, tearing ragged holes.

Pistols of Other Types.—The evolution of the pistol prior to the development of a satisfactory metallic cartridge (pin-fire, 1846) parallels so closely that of the contemporary shoulder weapon that the reader is referred for a discussion of this to SMALL ARMS, THE DEVELOPMENT OF. Subsequent to that date, it went through the same cycle of unbridled development as did the early cartridge rifle, every conceivable form being constructed and marketed. Thus there is the Belgian "harmonica" pistol, wherein a multi-chambered horizontally-moving breech-block, containing a very considerable number of pin-fire cartridges, is mechanically shifted, a chamber at a time, from right to left, or vice versa, through an aperture in the frame of the piece, each chamber in turn being aligned with its single barrel and so discharged. Then there is the German "Bar" pistol with two barrels superposed and a flat, rectangular, magazine block occupying the position of the cylinder in a conventional revolver. This is bored with four chambers, two upper ones, side by side, and two lower, one of these located directly below each of the upper. The double-action mechanism, actuated twice, discharges two of the chambers, one projectile emerging through the upper, one through the lower barrel. The magazine block is then manually rotated through an arc of 180 degrees, when the two other chambers come into alignment with the barrels and are ready to be discharged. And there are many other multi-shot pistols of the superposed barrel type (two, three and four or more barrels, one atop another) such as the Remington double deringer (U.S.A.), two-shot; the Marston (U.S.A.), three-shot; the Reform (Germany), four-shot, etc. In addition there are such oddities as the Belgian "gravity" pistol wherein a tubular magazine surmounts the barrel proper. When this is filled with cartridges and the muzzle of the piece tipped upward, thus allowing the rearmost charge in the magazine to approach the breech, the mere cocking of the hammer actuates an ingenious carrier by which it is transferred from magazine to chamber. Another tube-magazine type, closely approximating in its manner of operation the tube-magazine repeating rifle was the Remington (U.S.A.) repeating pistol of .32 calibre. There are also metallic cartridge pepper-boxes, popularized in the U.S.A. by such makers as Sharps, Bacon, Remington, Rupertus, etc., the first-named being widely copied in the British Isles. And apart from these numberless varieties designed for general use in defence and offence, there remains yet another infinity of types intended for special, and restricted, purposes. These include blank-cartridge pistols in single-shot, repeating-

THE LOCK OF A COLT AUTOMATIC PISTOL

be transferred from magazine to chamber. If now left unfired, the subsequent removal of the magazine leaves the charge in the chamber undisturbed, but all too many persons are forgetful of this and forthwith consider the arm unloaded and treat it as such. The "magazine safety" renders an accident impossible by locking the firing mechanism automatically immediately the magazine is withdrawn.

Revolver v. Automatic.—Though devotees of the automatic pistol have, ever since the invention of that type of weapon, predicted the early decline and disappearance of the revolver, there is as yet little evidence to indicate that their forecastings are soon to be fulfilled. The automatic has gained acceptance by the military in many countries, but in others of equal importance

pistol, revolver and automatic-pistol types, gas weapons for temporarily blinding an adversary, executed in every possible form from the standard revolver type to the camouflaged door key, fountain pen and policeman's truncheon. Also encountered are burglar-alarm pistols for attachment to door or window, usually firing blank ammunition but occasionally designed for ball or shot, trap pistols to destroy small game infesting country places, and discharged when the victim nubbles the bait attached, and signal pistols for military use.

PISTOLE. The French name given to a Spanish gold coin in use from 1537; it was a double *escudo*, the gold unit, and was worth 16s. 11½d. sterling. The name was also given to the *louis d'or* of Louis XIII of France; and to other European gold coins about the value of the Spanish coin.

PISTON: see STEAM ENGINE; INTERNAL COMBUSTION ENGINES; PUMP.

PITCAIRN, a borough of Allegheny county, Pennsylvania, U.S., 12 mi. S.E. of Pittsburgh, on the Pennsylvania railroad. The population in 1950 was 5,857; in 1940, 6,310 by federal census. Railway car shops and freight yards were established there. Steel freight cars and bricks are manufactured in the borough. This historic community was named Dirty Camp by Col. Henry Bouquet in 1763. The present borough was incorporated in 1894.

PITCAIRNE, ARCHIBALD (1652–1713), Scottish physician, was born at Edinburgh on Dec. 25, 1652. He took his M.A. degree at Edinburgh university in 1668, and after courses in Edinburgh and Paris he obtained in 1680 the degree of M.D. at Rheims. He began practice at Edinburgh, and in 1692 was appointed professor of medicine at Leyden. Among his pupils were Richard Mead and H. Boerhaave, and both of them attributed much of their skill to what they learned from Pitcairne. In 1693 Pitcairne settled once more in Edinburgh. He persuaded the Edinburgh town council to permit himself and certain of his medical friends to treat without fee the sick paupers in "Paul's Work," on condition of being allowed to dissect such of the bodies as were unclaimed by their relatives. In this way he may be said to have the credit of laying the foundation of the great Edinburgh school of medicine. He died on Oct. 20, 1713.

PITCAIRN ISLAND: see PACIFIC ISLANDS.

PITCH. The name of various substances of dark colour and of extremely viscid and tenacious consistency when subjected to heat. (O. Eng. *pic*, an adaptation of Lat. *pix*, *picis*, Gr. *πίσσα*, *πίττα*, allied with Gr. *πίτυς*, pine tree, Lat. *pinus*.) Strictly the term is applied to the resinous substance obtained as a solid residuum by the distillation of wood tar (see TARS, LOW-TEMPERATURE), or the nonresinous substance similarly produced from coal tar (*q.v.*). The name is also applied to the natural mineral substances; *i.e.*, asphalt or bitumen (*qq.v.*).

PITCH, MUSICAL. Pitch is that quality of a musical tone which permits it to be judged by the ear as high or low. It corresponds roughly to the logarithm of the frequency, is somewhat affected by intensity and needs a minimal time for recognition.

As a function of frequency, pitch is closely related to interval. An interval between two tones may be expressed by the ratio of their frequencies. In music theory the octave, with ratio 2:1, is taken as the primary unit of interval. Although a sequence of octaves thus has linear significance, the respective frequencies increase by powers of two. An interval, therefore, is a logarithmic measure of the ratio of two frequencies, to the base two. In occidental music the octave is divided into 12 equal semitones, whence the semitone, with ratio $2^{\frac{1}{12}}$:1, becomes the practical logarithmic measure of interval. For scientific purposes, A. J. Ellis' cent, $2^{\frac{1}{1000}}$:1 is invaluable.

It might seem, therefore, a simple matter to correlate pitch with

frequency. With a note of fixed frequency as standard, a note of some other frequency will be a certain number of octaves higher or lower, plus a certain number of semitones or cents. There is no uniform method of designating octaves. In one system the note *c'* means middle C on the piano, having 256 vibrations per second (v.p.s.) in what is known as philosophical pitch, so called because it provides integral frequencies for C in every octave. But this same note has often been called *c*, and in contemporary acoustical practice *C*₄ or *C*₃. Among musicians the note an octave above middle C is treble C and above it comes C in alt; below middle C comes tenor or viola C, below it 'cello C, pedal C and subpedal C.

The frequency of subpedal C is 16 v.p.s. which is about the lower limit of audibility. The upper limit is between 15,000 and 20,000 v.p.s., some two octaves above the highest note on the piano. Thus the range of frequencies heard by the normal ear is roughly ten octaves. If the ear were to respond uniformly throughout this range, pitch could indeed be correlated with frequency or interval. From experimental data S. Smith Stevens constructed a graph in which subjective pitch is plotted against interval, the logarithm of frequency. His pitch unit is the mel (from melody), which is defined as .001 the pitch of 1,000 v.p.s. The graph is concave until about 1,500 v.p.s., nearly straight, at a 66° angle, from 1,500 to 6,000 v.p.s., after which it becomes slightly convex. From this study, musical intervals, as expressed by frequency ratios, become subjectively larger as the frequency increases, throughout the normal musical range. The peak comes close to the highest note on the piano (4,000 v.p.s.), after which there is a decided drop. Thus pitch is a frequency function which is almost linear at low frequencies (the concave part of the curve), and almost logarithmic at high (the straight part).

Pitch is affected by loudness. A pure tone with constant frequency decreases in pitch as its loudness level increases. Experiments conducted by Harvey Fletcher showed a decrease for all frequencies up to 2,000 v.p.s., after which there was a very slight rise in pitch with intensity. The greatest dip came in the region of 200 v.p.s., about G below middle C, where an increase in intensity from 40 db (decibels) to 100 db (from a quiet room level to that of a boiler factory) reduced the heard pitch by almost 10% or 1.7 semitones. For complex tones, the heard pitch seems to be determined by the higher partials, which lie in that part of the range in which the fall of pitch is small. Thus the musician has nothing to worry about, for he does not ordinarily produce pure tones.

A certain time is needed for the ear to perceive a tone as having pitch. With the duration of .001 sec., any frequency is heard as a click. With the duration increased somewhat, the sound appears as a noise of indeterminate pitch. For 1,000 cycles, the threshold for complete pitch recognition is .012 sec., but it increases greatly for lower frequencies. This phenomenon is of little consequence in musical performance. Seldom are staccato notes played as short as $\frac{1}{17}$ sec., the threshold for the lowest G on the piano (50 v.p.s.), and when composers write very rapid notes at a low pitch, they do not desire clarity.

The word pitch is often taken to mean pitch level, the thing the French call "diapason." So long as musical instruments were principally of the stringed type, as in ancient Greece, there was no fixed pitch standard. Even in the Renaissance, instruments were tuned to any convenient pitch. With wind instruments, there was less pitch variation than with the strings, and when these instruments were played in combination it was necessary for them to have some standard, even if it was purely local. The organ has always had a stabilizing effect upon pitch, since its pitch is fixed within narrow limits when it is built.

Alexander J. Ellis attempted to reconstruct the pitch level of old organs by making small-scale models of pipes whose dimensions were known. A safer indication of prevailing pitch is the compass of the vocal music for a particular time and place. The early scale of the Greeks, for example, was of two-octave extent, from A to *d*. For untrained tenor and bass voices at the modern pitch this range would be too high by approximately a tone. From this it may be concluded that the Greek "diapason" was about a tone lower than ours.

Similar reasoning may be applied to what Arnold Schlick wrote

about organ pitch in the early 16th century. He advocated a pedal-board extending from F to ϵ , a compass of a 12th, so that the union plain song melodies might be played on the pedals. But the 12th that mixed male voices can sing with any ease in modern times is A to ϵ . Hence Schlick's organ must have been about a major third higher than modern pitch.

Internal evidence shows that at least three different pitches were prevalent in Tudor England. The secular vocal music was at modern pitch, but the church music was sung more than a tone higher and thus should be transposed up a tone. The pitch of the virginals was three semitones lower, but this makes little difference in modern performance.

In Germany in the early 18th century there were two important pitches and two of lesser moment. The normal pitch was chamber (*Kammerton*), used by voices, strings, and most woodwinds. Choir pitch (*Chorton*) was a tone higher than chamber, and was used by organs and trumpets. (The key of D was signally the trumpet key for Bach and Handel.) *Cornett-ton*, the townpipers' pitch, was a semitone higher than *Chorton*, and *tief Kammerton*, a semitone lower than *Kammerton*, belonged to oboes.

The tuning fork was invented in 1711 by Handel's trumpeter, John Shore. It helped tremendously to standardize pitches, and knowledge of the precise pitches used in various musical centres after that time rested upon a much surer basis than Ellis' measurement of organ pipes. Handel's own fork gave an A of 422.5 v.p.s., which is .7 semitone lower than modern pitch, and Mozart's was practically identical.

At the Congress of Vienna in 1814 the emperor of Russia presented new and sharper instruments to an Austrian regiment of which he was honorary colonel. This band became noted for the brilliancy of its tone, and another band in 1820 received even sharper instruments. Since opera houses were largely dependent upon military bands for wind players, they were forced to adapt their pitch to a higher standard. And so during Beethoven's lifetime the pitch in Vienna rose close to modern pitch, and by the 1850s had reached 456, .6 semitone higher than that of the 20th century and 1.3 semitones higher than Mozart's pitch.

Meanwhile in England pitch was also rising. In the 1820s Sir George Smart, conductor of the Philharmonic concerts, approved a fork giving 433. But 20 years later, with Sir Michael Costa the conductor, the pitch had risen to 452.4, practically the same as the "sharp Vienna pitch." The "high Philharmonic pitch" continued to be used for British bands until 1928. In the United States the Steinway pitch of the 1880s went as high as 458, and this "concert pitch" was still common even 40 years later.

A warning voice against rising pitch was raised in 1834 when an international congress of physicists adopted J. H. Scheibler's 440. But it had no practical effect. In 1858 the French government appointed a joint committee of musicians and physicists to agree upon a lower standard of pitch. Their notable report in Feb. 1859 advocated a "diapason normal," to be set by a tuning fork at 435 v.p.s. (actually 435.4) at 15° C. (59° F.). At the Vienna Conference of 1885, 435 became International pitch. However, it was not until 1896 that England adopted a "new Philharmonic pitch" of 439 at 20° C. (68° F.). The British Standard Concert pitch adopted in 1939 was 440, the standard adopted by the American Federation of Musicians some twenty years earlier.

Controversies continued to rage over the merits of 435 and 440. Many writers consider them equivalent. The pitch of wind instruments rises with temperature. At the frequency for ϵ this rise, for flutes and flue organ pipes, is .43 v.p.s. for 1° F. (It is less for other wind instruments.) Thus the rise in temperature from 59° to 68° F. would raise a 435 pitch to 439, the "new Philharmonic pitch," and a temperature of 70° F. would bring it up to 440. But Llewellyn S. Lloyd pointed out that the original French decree was for an absolute pitch—435, whatever the temperature of the concert hall. It was only the standard tuning fork (whose pitch would fall insignificantly with temperature rise) that was to be at 435 at 15° C. However, if a wind instrument has been constructed for a certain pitch level at a specified temperature, the player may find it impossible to adjust its pitch to a level as low as this when playing in a hall with a substantially

higher temperature. The British workshop temperature, therefore, is supposed to be held at 68° F., but should be at 72° in the United States, these temperatures reflecting the difference in concert-hall temperatures for the two countries.

The above term "absolute pitch" is often used in a different sense than to mean a fixed standard. A person who can identify a heard frequency immediately and with great accuracy is said to possess absolute, or perfect, pitch. Some investigators believe that, as a refinement of a widespread ability, it can be improved by training. Albert Bachem rejected this view, calling such a limited ability "pseudo-absolute pitch." His subjects had possessed their uncanny sense of pitch from childhood, with an accuracy that averaged .1 semitone. Although Bachem explained absolute pitch in terms of tone height and "chroma", it remains one of the most puzzling and fascinating things connected with pitch.

(J. M. Br.)

PITCHBLEND: see URANINITE.

PITCHER, MOLLY (1754–1832), sobriquet of the American Revolutionary War heroine MARY LUDWIG HAYS MCCAULEY who carried water to American soldiers at the battle of Monmouth on June 28, 1778.

Born on a farm near Trenton, N.J., on Oct. 13, 1754, the daughter of a German immigrant, John George Ludwig Hass (or Has), she was married in 1769 to John Caspar Hays in Carlisle, Pa. She joined her husband, who was a soldier in the artillery, on the field of battle at Monmouth and not only distinguished herself by supplying water to the troops on the extremely hot day but also was reported to have manned Hays's cannon after he was prostrated by the heat. Molly and her husband returned to Carlisle after the war.

Hays died in 1789 and Molly later was married to George McCauley, but the marriage proved unhappy. In Feb. 1822 the Pennsylvania general assembly recognized her services by awarding an annuity to her.

She died on Jan. 22, 1832.

PITCHER PLANTS are certain carnivorous (or insectivorous) plants, the leaves of which bear pitcher-like structures or are as a whole pitcher-like in form. The plant usually thought of in this connection is *Nepenthes*, of the family Nepenthaceae, of which genus there are about 60 species native to tropical Asia, the Philippines, north Australia and Madagascar. The Asiatic islands are especially rich in species, particularly Borneo. They are lax shrubby plants, creeping in the soil or climbing on the surrounding vegetation. While many are jungle plants, some affect relatively drier hillsides. The climbing is done by means of strong tendrils which are elongations of the leaf midrib. These under suitable conditions produce at the apices the pitchers, which stand upright at the hanging ends of the tendrils.

The pitcher is a development of the end of the tendril and is in form either tapering tubular or variously expanded either at the base or upper part; or they may be goblet-shaped. The pitcher usually shows a pair of wings, running longitudinally on the ventral aspect of the outer surface which are extensions of the margins of the leaf base. The mouth of the pitcher has a corrugated rim of various dimensions in different species. This rim consists of the outturned pitcher margin flanked by an outgrowth on its inner surface. These two, in maturity, are indistinguishable and form one organ, the peristome. Its surface is very firm, shining and broken into transverse ridges, both primary and secondary in size, parallel to each other and prolonged at the inner edge of the peristome as teeth, beneath each of which is a large nectar gland. Above the mouth is the lid or operculum which is immobile. It varies in size according to the species from a narrow process to a

huge heartshaped expansion, overshadowing the mouth. A study of the development of the pitcher, especially in the seedling or in forced small shoots, shows that the inflated portion is a development of the midrib of the leaf, while the wings, which are especially well developed under some circumstances, represent the upwardly extended leaf base. In the mature type of pitcher there is an apparent separation of the wings from the proximal part of the leaf base by the tendrils, along which the wings, readily seen in seedling

above the level of the surface in general, they have been interpreted as stumbling blocks to render the hold of insects' feet insecure. In any event the waxy surface crumbles under their feet, and they fall to their doom. This area has been called the "conducting surface," as distinguished from that below it, the "detentive" region, which could be called the digestive region, since the surface here is crowded with digestive glands, each partly covered with a sheltering overhang of epidermis. Of these there may be as many as 6,000 per sq.cm.

In some pitchers there is no waxy surface, though the two kinds of pitchers may occur on the same plant in some species. Insects which have been lured to the mouth of the trap and attempt to obtain nectar from the marginal glands of the peristome or from the underside of the lid, can, on losing foothold, fall into the trap or pitfall. If they can walk in safety on the peristome, they find it impossible on entering the trap to walk on the waxy surface. Falling into the fluid which as first secreted is bland, the glands are stimulated to secrete a weak acid and a digestive (proteolytic) enzyme when insects are present. The nitrogenous parts of the insect bodies are digested, leaving the chitinous exoskeletons to accumulate. The products of digestion are absorbed by the walls of this region of the pitcher.

The process is essentially similar to that in the sundews (*Drosera* spp.), *Pinguicula*, and other carnivorous plants.

The presence of a digestive enzyme does not preclude the use of the fluid, enriched by insect bodies, by commensal organisms as a nidus for their growth and nourishment. A rich flora and fauna consisting of desmids, diatoms, protozoa and various kinds of insect larvae have been discovered and described. It is held by some that these organisms are protected from the attacks of the digestive ferments by the presence in their bodies of antienzymes, as has been claimed for endoparasites in the animal body. The small, primitive, monkeylike insectivorous tarsier (*Tarsius spectrum*) is believed to rob the pitchers of their contents. One species of *Nepenthes* (*N. bicalcarata*), has sharp, clawlike hooks, developed from the inner ends of the peristome just beneath the lid (see fig. 2).

These have been regarded by some as an adaptation for catching the tarsier if he tries this game on the species.

Another species, *N. intermedia*, has projections of similar dimensions in the same situation, but in this case they are too weak to act in such manner.

Sarracenia, another genus of pitcher plants, is represented by eight or nine species (Wherry). They naturally fall into two groups, distinguished by the posture of the leaves. Two species have recumbent leaves, *S. purpurea* (sidesaddle plant) and *U. psittacina*. The leaf of the former suggests the horn of plenty (see fig. 3). In the other the leaf lies in a nearly prostrate position, and the entrance lies horizontally and is hidden beneath a

hood. In other species the leaf is trumpet shaped (slightly curved in *S. minor*) with the lid either upright or more or less inclined over the mouth. The colour varies considerably from yellow-green (*S. flava*) to deep green variously masked by red, the intensity of which depends in part upon the situation, whether in bright sunlight or shade. The plant consists of a cluster of leaves springing from strong stolons and is herbaceous. The leaf has a broad sheathing base surmounted by a short stalk widening into the pitcher, which develops from the back (abaxial)

part of the leaf base, the edge of which is continuous. On the ventral aspect of the pitcher arises a wing, while from the back of the mouth a lamina-like expansion, the lid, arises. The outer surfaces, especially that of the wing leading to the entrance, are supplied with nectar glands which during vigorous growth and for some time

FIG. 1.—PITCHER PLANT (*NEPENTHES GRACILIS*): SHOWING GENERAL HABIT OF GROWTH; AND A, B AND C MINUTE STRUCTURE OF PITCHER PLANT

leaves, are vestigial. The lid has been thought to consist of two fused leaflets, but a more recent view is that it is a transverse growth.

The short straight or curved process on the back of the pitcher just below the lid represents the organic apex of the leaf.

The size of the pitcher varies widely in different species, from the size of a thimble to that of a pint pot or sometimes even larger. The colour also varies considerably, even in different pitchers on the same plant, according to age, light exposure or soil conditions. It may be yellowish to dark green, variously marked by red, and on the peristome the red colouring forms sharp transverse bands. Some pitchers are merely pale green. They are more or less invested by a rough pubescence of stiff branching hairs, especially when young.

Insects, particularly ants, are attracted to the plant by many deep nectar glands which occur in scattered positions on the stems and leaves, including the tendrils. These insects can hardly escape finding the nectar glands which occur plentifully on the inner surface of the lid in most species, and thus are lured to the mouth of the pitcher, about which the peristome forms a perilous foothold, especially for insects trying to reach the nectar secreted by the large glands found on its inner edge. Even if the surface of the peristome offers no impediment to some insects, as in the case of small ants, there is in most pitchers a curious waxy (glaucous) surface clothing the upper half of the interior of the pitcher. This area has peculiar stomata which appear under low magnification as crescentic cells—guard cells distorted out of position and hiding in each case its companion guard cell beneath it. There is, moreover, no opening. Since the visible guard cells stand a little

FIG. 2.—PITCHER PLANT (*NEPENTHES BICALCARATA*), A PLANT WITH PITCHERS ONLY AT THE END OF THE LEAVES

during maturity exude nectar which attracts insects to the entrance. The inner surface of the lid and the upper portion of the interior of the pitcher have many glands also; those on the lid and forward edge of the pitcher mouth exude nectar while those within the pitcher are in all probability digestive in function. The

foliage leaves, ovate and acute in form, and pitcher leaves, the latter having very much the form of a loose slipper, as stated by A. G. Hamilton, an Australian student of this plant. The simile is apt if we think of the heel as turned up; this is the lid which overhangs the entrance.

The pitcher is about the size of a thumb and has much the shape of the distal half of a large thumb. The mouth is transversely oval and is guarded by strong, hook-shaped claws pointing inward and downward, graduated in size, the largest being in front. Over-shadowing the entrance is the lid which has several white strips (fenestrations) radiating from its base, with green-red strips between. These, we may imagine, give the insect visiting the rim the impression of a way of escape but serve only to deflect him into the inside of the pitfall trap. The inner surface of the lid is lined with striated hairs pointing toward its base and hence toward the pitcher's interior. Within the pitcher is a thickened zone (collar) of the wall which ends abruptly a short distance below in an overhanging shoulder, an impediment to escape. Both on the lid and collar are found many nectar glands. The expanded lower portion of the pitcher is strikingly marked by the presence of two large kidney-shaped patches where the wall is thickened, one on each side and placed obliquely. These are glandular in nature. The epidermis consists of cells with strongly wavy walls, interspersed with curious stomata, the guard cells of which are widely spread and immobile. These stomata are plugged by a soft cellulose wall of a cell below and are probably water-excretory, as experiment has indicated. Here also occur large glands, of a structure similar to others of smaller, graduated sizes, scattered throughout most of the rest of this portion of the pitcher. That these glands secrete a digestive agent seems likely from the work of W. J. Dakin.

The external surface of the pitcher bears wings. One runs along the middle line and is doubled along the outer edge. Another two, one on each side, run obliquely along the sides. Two others, quite low and not readily seen, run from the edges of the lid to the stalk, which is attached to the pitcher near the lid; in this feature *Cephalotus* differs from the pitchers of all other species. The development of the pitcher shows that it is morphologically upside down.

There are usually produced besides the extreme forms of leaves, foliage and pitcher, intermediate forms which throw light on the morphology of the pitcher.

Genlisea, an aquatic genus with several species in tropical Africa and Brazil, is a relative of *Utricularia* (q.v.). It has traps which are of the pitcher type; they are not, however, pitfall traps, but of the lobster-pot type. Charles Darwin likened them to eel traps. The plants are small and herbaceous, consisting of a cluster of leaves arising from a short stolon, buried in mud. The leaves are of two kinds: foliage leaves, usually near-spatulate in shape, and trap leaves of peculiar design. The latter leaf consists of a stalk on which arises a bulbous, hollow enlargement. From its top extends a tube, the extremity of which produces two arms which are twisted like corkscrews. They are ribbon-shaped extensions of the tube folded longitudinally and with the edges of the ribbon fixed and held a certain distance apart by large cells, placed like buttons. The interrupted slit thus left permits the entrance of minute animal forms (small crustaceans, worms, larvae, as in *Utricularia*). The escape of the prey after entrance is prevented by numerous sharp, stiff hairs, intermixed with many glands, which may be

BY COURTESY OF THE TRUSTEES OF THE BRITISH MUSEUM

FIG. 3.—SIDE SADDLE FLOWER (*SARRACENIA PURPUREA*): SHOWING LEAVES, THE WHOLE OF WHICH FORM THE PITCHERS; AND A, B, AND C SHOWING THE MINUTE STRUCTURE OF PITCHERS (A AND C FROM S. FIG.)

lid is armed with strong, downward pointing hairs, and it is a matter of observation that flies attempting to garner the nectar here almost invariably fall into the pitcher. Below its mouth the surface is smooth and glistening. The upper zone immediately surrounding the pitcher mouth is beset with nectar glands and is usually coloured red in *S. purpurea*. The wide zone below has numerous digestive glands, according to J. S. Hepburn and his associates. Below this occurs a "detentive" zone where the surface bears numerous stiff, straight, retrorse hairs which effectively prevent the escape of insects. The fluid of the pitcher has a ready wetting power so that insects become quickly submersed and drown.

The digestion of the prey is partly by the action of digestive ferments (Hepburn *et al.*) and partly by bacterial action, in one or two species perhaps wholly.

The chitinous coverings of insect bodies are indigestible, and they accumulate till the leaf dies. Doubtless when this occurs some material is released to the soil and helps to manure it. The accumulated mass of insect bodies offers nutriment to commensal insects which take advantage of the situation to lay their eggs within the pitcher where the larvae live on the putrid mass. Birds often slit open the pitchers and feed on the living larvae. In the fluid a mosquito (*Wyeomyia smithii*) passes its immature stages and is believed to be confined to this habitat. The occurrence of clear fenestrations on the lid (*S. drummondii*), on the lid and back of the upper dorsal part of the pitcher wall (*S. minor*) or on the hood and ventral part of the pitcher wall (*S. psittacina*) is an interesting feature and is seen also in *Darlingtonia* (q.v.). These window-like areas serve to attract insects.

Cephalotus follicularis is a native of southwest Australia, the town of Albany being at about the centre of its restricted range. It has the same habit as *Sarracenia* but is a smaller plant. Its leaves are of two kinds, growing in a rhythmic alternation: the

FROM "CURTIS' BOTANICAL MAGAZINE" AND LLOYD, "THE CARNIVOROUS PLANTS" (CHRONICA BOTANICA CO.)

FIG. 4.—PITCHER PLANT (*CEPHALOTUS FOLLICULARIS*) SHOWING LEAVES, PITCHERS AND TALL FLOWER STEM WITH SMALL FLOWERS. AT LEFT OF STEM IS A LATERAL VIEW OF A TRAP OR PITCHER; AT RIGHT, VIEW OF THE INTERIOR OF THE PITCHER

merely mucilaginous. Both these appendages occur in curved rows, rendering the interior of the arms curiously complicated. Passing down the arms, the prey at length passes into the tube, also lined with long, slender downward pointing hairs so arranged that they form what would be, if large enough, a lobster pot. In this region are digestive as well as mucilage glands, in transverse rows. The prey finally reaches the bulbous expansion, which has two internal ridges carrying numerous digestive glands, and here the process of disintegration is completed. While no experimental work has been done to demonstrate the presence of enzymes, the rapid dissolution of the bodies of prey and the analogy with *Utricularia* make it seem fairly certain that such enzymes are produced.

Like *Utricularia*, *Gentileia* grows only in wet places, partly or wholly submerged, and anchored in the substrate.

See F. E. Lloyd, *The Carnivorous Plants* (1942), in which a full bibliography may be found. (F. E. L.)

PITCHSTONE, in petrology, a glassy igneous rock having a resinous lustre and breaking with a hollow or conchoidal fracture (Ger. *Pechstein*, from its resemblance to pitch). It differs from obsidian principally in its rather dull lustre, for obsidian is bright and vitreous in appearance; pitchstones also contain water in combination amounting to from 5 to 10% of their weight. The majority of the rocks of this class occur as intrusive dikes or veins; they are glassy forms of quartz-porphry and other dike rocks. Their dull lustre may be connected with the great abundance of minute crystallites and microlites they nearly always contain; these are visible only in microscopic sections, and their varied shapes make pitchstones very interesting to the microscopist.

Although pitchstones of Devonian age are known (e.g., the glassy dacite of the Tay bridge in Scotland and the andesite-pitchstones of the Cheviots), most of them are Tertiary or recent, as like all natural glasses they tend to crystallize or become devitrified in course of time. In some of the older pitchstones the greater part of the mass is changed to a dull felsitic substance, while only nodules or kernels of unaltered glass remain. Some are very acid, containing 70% to 75% of silica, and have close chemical affinities to granites and rhyolites; others contain more alkalis and less silica, being apparently vitreous types of trachyte or keratophyre; others have the composition of dacite and andesite, but the black basaltic glasses are not usually classified among the pitchstones. Very well-known rocks of this group occur at Chemnitz and Meissen in Saxony. These rocks are brown or dark green in colour, very frequently perlitic, and show progressive devitrification starting from cracks and joints and spreading inward through the mass. For a long time the pitchstone dikes of Arran, Scot., have been famous for the great beauty and variety of skeleton crystals they contain; they are dull green in hand specimens; some of them contain phenocrysts of feldspar, augite, etc., others do not, but in all there is great abundance of branching feathery crystalline growths in the ground mass, minute crystalline rods being built together in aggregates which often recall frost patterns. It is supposed that they consist of hornblende. In addition to these larger growths there are many small microlites scattered through the glass, also hairlike trichites and fine rounded globulites. When phenocrysts are present the small crystals are planted on their surfaces like grass on a turf-covered wall. These pitchstones are believed to proceed from the great eruptive centres of early Tertiary times in western Scotland. Another pitchstone of the same period forms a great craggy ridge or scuir in the island of Eigg (Scotland). In chemical composition this latter rock resembles the trachytes rather than the rhyolites; in Eigg and Skye there are many dikes of pitchstone, mostly of intermediate rather than of acid character, all connected with the great eruptive activity which characterized that region in early Tertiary times.

The following analyses give the chemical composition of a few well-known pitchstones:

	SiO ₂	Al ₂ O ₃	Fe ₂ O ₃	MgO	CaO	Na ₂ O	K ₂ O	H ₂ O
Meissen	72.42	11.26	0.75	0.28	1.35	2.86	3.80	7.64
Corriegills . . .	72.07	11.26	3.24	tr.	1.53	0.61	5.61	5.45
Scuir of Eigg . .	65.81	14.01	4.43	0.89	2.01	4.15	6.08	2.70

The first two of these contain much water for rocks, the ingredients of which are but little decomposed. They are of acid or rhyolitic character, while the third is richer in alkalis and contains less silica; it belongs more naturally to the intermediate rocks (or trachytes).

(J. S. F.)

PITHECANTHROPUS, the name given to a fossil man (*P. erectus*) discovered by Dr. Eugene Dubois in 1891-92, on the bank of the Solo river, near Trinil, Java. The remains consist of a thigh-bone, two teeth and the upper part of a skull. The skull is low, with a capacity of about 800 cu.cm. and with strong superciliary ridges; the teeth are large and the femur is quite human.

After 1936 parts of 3 more skulls were found near the original site. In northern China skulls and skeletal remains of about 40 individuals of the closely related Peking man were discovered. Altogether they confirm the restoration based on the original skull cap and indicate that Dubois' fragments belonged to a primitive human being with numerous apelike features. The age of *Pithecanthropus* is Middle Pleistocene.

See E. Dubois, *Pithecanthropus erectus* (1894), Smithsonian Report for 1898; A. Keith, *Antiquity of Man* (1915); F. Weidenreich, "Man or Ape," *Nat. Hist. Mag.*, vol. 45 (1940). (J. E. H.L.)

PITHIVIERS, a town of north central France, in the department of Loiret, 28 mi. N.N.E. of Orléans, on the railway to Malesherbes. Pop. (1940) 6,916. The town is an important centre for the saffron of the region of Gâtinais. The shrines of St. Solomon (9th century) and of St. Gregory, an Armenian bishop (10th), formed the nucleus of the town; and the donjon built in the 10th century for Héloïse, lady of Pithiviers, was one of the finest of the period.

PITHOM, one of the "treasure cities" stated to have been built for Pharaoh by the Hebrews in Goshen during the Oppression (Exod. i, II). We have here the Hebraized form of the Egyptian Petôm, "House of (the sun-god) Etôm," in Greek, Patûmos, capital of the 8th nome of lower Egypt and situated in the Wadi Tumilat on the canal from the Nile to the Red sea. Succoth (Egyptian Thuket) was identical with it or was in its immediate neighbourhood. The site, now Tell el Maskhuta, has yielded several important monuments, including the best preserved of the trilingual stelae of Damus which commemorated his work on the canal.

PITIGLIANO, a town in Italy, province of Grosseto. Pop. (1951) 5,760 (commune). It is the cathedral city of the bishopric named after the neighbouring town of Sovana, and was originally a fief of the countship of Sovana, which in 1293 came by marriage into the possession of the Orsini. In 1410 Sovana was taken by the Sienese, but the Orsini retained Pitigliano, Gentile Orsini assuming the title of count. In 1562 the Medici of Florence seized part of their territories, and acquired the rest by exchange in 1580. The Orsini stronghold still stands in the town, which is perhaps identical with the Etruscan Statonia.

PITMAN, SIR ISAAC (1813-1897), English phonographer, was born at Trowbridge, Wiltshire, on Jan. 4, 1813. He started in life as a clerk in a cloth factory, but in 1831 he was sent to a training college for teachers. After 11 years of teaching in elementary schools he opened a private school in Bath. In 1829 he took up Samuel Taylor's system of shorthand and became an enthusiast in developing the art of phonography. In 1837 he drew up a manual of Taylor's system and offered it to Samuel Bagster (1771-1852). The publisher did not accept the work, but suggested that Pitman should invent a new system (see SHORTHAND) of his own. The result was his *Stenographic Soundhand* (1837). Bagster's friendship and active help had been secured by Pitman's undertaking to verify the half-million references in the *Comprehensive Bible*, and he published the inventor's books at a low price, thus helping to bring the system within the reach of all. Pitman established at Bath a Phonetic institute and a *Phonetic Journal* for this purpose; he printed in shorthand a number of standard works, and his book *Phonography* (1840) went through many editions. He was an enthusiastic spelling reformer, and adopted a phonetic system which he tried to bring into general use. In 1894 he was knighted. He died at Bath on Jan. 12, 1897.

His Life was written in 1902 by his brother Benn Pitman (1822-1911) and by Alfred Baker in 1908.

PIT PONY. The pit pony is usually a small pony—14 hands high and under—used for hauling the tubs for the conveyance of coal from the working face of the coal seam to a point, variously termed the "flat," "double-parting," "station" or "landing," where the tubs are made up into "sets" or trains and conveyed, either by horses or, more commonly, by mechanical haulage, to the shaft bottom. That is to say, the pit ponies ply between the face and flat, bringing the full tubs out from the hewer and serving him with empty tubs. The use of pit ponies has decreased with the extended development of electrically driven haulage underground.

PIT-SHAFT: *see* COAL AND COAL MINING.

PITT, THOMAS (1653–1726), British East India merchant and governor of Madras, usually called “Diamond Pitt,” was born at Blandford, Dorset, on July 5, 1653. From his headquarters at Balasore, he engaged in trade in opposition to the East India Company, whom he opposed also in the law courts. Unable to check him the East India Company took him into its service in 1695, and in 1697 he became president of Fort St. George, or Madras. While in India Pitt bought the fine diamond which was named after him; in 1717 he sold this to the regent of France, Philip duke of Orleans, and it is now the property of the French government. During his stay in England Pitt acquired the manor of Old Sarum, and for a short time he represented this borough in parliament. After his final return from India in 1710 he again became member of parliament for Old Sarum. He died at Swallowfield, near Reading, on April 28, 1726. His eldest son, Robert, was the father of William Pitt, earl of Chatham (*q.v.*); and of Thomas Pitt (d. 1761), whose son became the first Lord Camelford; his second son, Thomas Pitt (c. 1688–1729), having married Frances (d. 1772), daughter of Robert Ridgeway, 4th earl of Londonderry (d. 1714), was himself created earl of Londonderry in 1726.

See Sir C. N. Dalton, *Life of Thomas Pitt* (1915).

PITT, WILLIAM (1759–1806), English statesman, second son of William Pitt, earl of Chatham, and of Lady Hester Grenville, was born at Hayes, near Bromley, Kent, on May 28, 1759, in the year of the pinnacle of his father's glory. Both because of his extreme delicacy and because his father was an early critic of the public school system, he was educated at home under the tutorship of the Rev. Edward Wilson of Pembroke Hall, Cambridge, and the earnest supervision of Chatham himself—a plan which tended to the intensive development of the child's unusual precocity. Before he was ten years old he was a good classical scholar; at 13 he had composed a strange political tragedy *Laurentino, King of Chersonese*. In Oct. 1773, in his 15th year, he went into residence at Pembroke Hall, Cambridge, where his tutor was the Rev. Dr. George Pretyman (he changed his name in 1803 to Tomline), to whom Pitt in later years awarded the bishopric of Lincoln, and at the last bequeathed his papers: and who in return became his pupil's first biographer. Pitt had not been at Cambridge long when he fell seriously ill and was obliged to return home. It was then that the family physician, Dr. Anthony Addington prescribed that generous consumption of port wine which was to become the habit of a life. He returned to Cambridge in July 1774; and in 1776, by the privilege of his birth as the son of a peer, graduated as a master of arts without examination. That year saw the Declaration of American Independence, and the next the battle of Saratoga. On April 7, 1778 Pitt was the witness of his father's last dramatic utterance in the House of Lords. A month later Chatham died. Pitt was left with an income of £300 a year; he began to keep his terms at Lincoln's Inn; was called to the bar on June 12, 1780 and joined the western circuit. At the general election in September Pitt was defeated for the University of Cambridge but was returned for Sir James Lowther's pocket borough of Appleby. He entered parliament on Jan. 23, 1781: he was not yet 22 years old.

Parliament.—Pitt was attached to that section of the opposition which had followed his father, and was now led by Lord Shelburne. His maiden speech on Feb. 26 was made in support of Burke's Bill for economical reform, and produced a series of famous eulogies, Lord North admitting it the best first speech he had ever heard, and Burke, with even greater prodigality, declaring him “not a chip of the old block but the old block itself.” A year later, when North's ministry was near its fall, Pitt had the self-confidence to announce in the House of Commons (March 8, 1782) that, should he conceivably be asked to join the new ministry, he would never accept a subordinate position in it; nor did he alter his mind when Rockingham, shortly afterwards offered him certain well-paid but unimportant posts, and even though one of them—the vice-treasurership of Ireland—had been held by Chatham before him.

As a private member Pitt now supported a new version of

Burke's reform project, a measure for shortening the duration of parliaments, and another for destroying bribery at elections. On May 7 he presented his own motion for a select committee to inquire into the state of the representation. It was only defeated by 20 votes. Shortly afterwards the death of Rockingham on July 1 provoked a major crisis. The king appointed Shelburne as his successor. Fox, Lord John Cavendish and Burke immediately refused to serve with him; whereupon Shelburne turned to Pitt, who on July 6 accepted the office of chancellor of the exchequer.

The Shelburne Ministry.—The ministry was only to last until the following February. On Jan. 20, 1783, the preliminaries of the Peace of Versailles were signed, and provided the opposition with an easy target. It was essential for Shelburne to obtain more support, and on Feb. 11, by agreement with his chief, Pitt visited Fox to invite him to return to the ministry. Fox replied that he would only serve on the condition that Shelburne resigned the premiership, whereupon Pitt replied “I did not come here to betray Lord Shelburne.” The incident is important. It marks the beginning of the ceaseless political warfare between Fox and Pitt; it marks the end of the Shelburne ministry, and the origin of the coalition between Fox and North. Speaking of North's Government only in the previous year, Fox had declared “From the moment when I shall make any terms with one of them, I will rest satisfied to be called the most infamous of mankind,” and he had loudly demanded their impeachment: yet he who had poured his blistering scorn upon North's conduct of the war, now joined with North in execrating the terms of the peace. The ministry was defeated (Feb. 21) and two days later Shelburne resigned. For a month the king sought to escape the coalition. But Pitt, who was pressed to accept the Treasury preferred to bide his time, and North could not be lured from Fox. On April 2 the Fox-North coalition under the nominal leadership of the duke of Portland took office.

The Coalition Ministry.—On May 7 Pitt brought forward resolutions for checking bribery at elections, disfranchising corrupt constituencies, and increasing the number of county and London members of parliament. The resolutions were refused by 293 to 149. On June 2 he brought forward another bill which passed the Commons but failed in the Lords, for reforming abuses in public offices: he instanced North's mysterious consumption of stationery, which totalled £1,300 and contained an item of £340 for whipcord.

During September and October Pitt visited France—his only venture outside his own country. In November parliament re-assembled and Fox immediately introduced his India bill. Passed in the Commons the measure was defeated in the Lords (Dec. 17) because George III. plainly informed the peers at large through Lord Temple that he should regard anyone who voted for the bill as his enemy. The Government very properly refused to resign. Whereupon the king, on Dec. 19, depending upon a barely literal interpretation of his constitutional rights, but reflecting by accident the wishes of his people, dismissed his ministers and appointed Pitt as first lord of the treasury and chancellor of the exchequer. The coalition had been jockeyed out of office, and it is not surprising that the House received the news of Pitt's appointment with mirth. It is mistakenly generous, however, to suppose that Pitt assumed office from pure altruism and without a certain confidence in the future. The strident Opposition no longer represented its constituency and Pitt knew it, and while they were wasting their breath deriding the “boyish prank,” Pitt was converting the electorate—voters who were to be more valuable to him than the voters in the House of Commons. Almost as important, the influence of the City and of the East India Company was on his side. Until the end of March he struggled on, continually defeated in the House, but steadily refusing to resign. Outside his popularity was growing, while the action of the Opposition in threatening to oppose even the votes of supply cast on them the obvious accusation of factiousness. The hostile majority diminished daily until on March 8 Fox's “representation” was carried by only one vote. On March 24 parliament was dissolved. The essential business had been forced

through. At the ensuing election some 160 of "Fox's Martyrs" were rejected. This was the answer to the charge of unconstitutional action: throughout the struggle Pitt had in fact represented the nation. Pitt was himself elected for Cambridge university, which he represented for the rest of his life.

PITT'S FIRST MINISTRY

Finance.—Finance was the first consideration. There was a heavy debt and the fiscal machinery was antiquated. Pitt floated a loan of £6,000,000, offering the tenders to public competition, and funded £6,600,000 of the floating debt. The loss to the revenue which had long resulted from the systematic evasion of the high protective tariffs he countered by a radical reduction of duties—that on tea being reduced from 119% to 12%. To meet the loss he increased the window tax, and many new taxes were instituted to touch the whole people. But he withdrew the tax on raw cotton, and pronounced it as his principle that "manufactures in general ought to be free from taxes."

Pitt, who had been one of the earliest students of Adam Smith, next attempted the establishment of free trade between England and Ireland. The Irish accepted his propositions (Feb. 7, 1785) but in England the measure was met by the organized opposition of vested interest, prejudice, and faction. Pitt was obliged to alter his original scheme, and in that form the Irish, disappointed and inflamed by Fox's subtle tongue, rejected it.

In 1786 Pitt introduced his sinking fund, a measure adapted from a scheme of Dr. Richard Price (*q.v.*). Economically it was undoubtedly mistaken, but it was believed to be a sovereign remedy, and it at least inspired public confidence.

On April 18, 1785, Pitt brought forward a bill proposing to suppress 36 pocket boroughs and to transfer their members to increase the representation of certain towns and counties. £1,000,000 was to be spent upon the purchase of the interests of the various owners. The bill, for which he eloquently pleaded, was rejected by 248 to 174.

India.—Pitt's India Bill, which had been rejected during the first struggle in the spring of 1784, was passed in the summer easily enough. Pitt's bill, unlike Fox's, left the ordinary patronage with the directors of the company while passing to the Crown the political control. Moreover, he had the tact and the wisdom to consult the company and to present as a final draft a measure to which he knew they were prepared to agree. The bill was not without serious defects—especially in its subordination of the governor-general not only to his council, but in all important concerns to the home Government. Warren Hastings resigned at once, and upon his return, his conduct of the Government was called in question. Pitt who had voted against the Rohilla charge (which was not carried) voted in favour of the Benares and the Begum charges. His action decided the issue. The motions were carried, and the impeachment pursued. Pitt has been heavily criticised for his conduct. But the truth that Hastings had been a great administrator could not disguise the fact that here was a patent scandal, which demanded inquiry. Indeed Hastings, through his agent in the House, had himself originated the discussions; and Pitt deliberately chose to support the Opposition in a matter where he honestly believed them to be right, instead of following the usual custom of opposing whatever measure the Opposition proposed.

The Regency Question.—In Nov. 1788 the king's illness provoked a crisis which might have ended Pitt's political career. There was a traditional enmity between the Hanoverian monarchs and their sons, and the whole influence of the prince of Wales (doubly hostile because Pitt would not pay his debts), was directed to the cause of the Whigs. The king being insane it was essential to appoint a regent, and Pitt was inevitably agreed that there could be no other candidate for the office than the prince of Wales. The point at issue lay in the claim of Fox and his party that the prince had a prerogative right to the position. Pitt claimed that he could only become regent by act of parliament, and drew up that act so as to restrain the regent from making peers or granting pensions, while the king's person and household and the patronage of the Crown were to be placed under the direction of

the queen. The bill passed the Commons (Feb. 5, 1789) and while it was under discussion in the Lords the king recovered. The situation had been dangerous, for though the resolutions had been carried, there had been much uneasiness among Pitt's followers. Pitt himself believed that he would be unable to retain office and would have to resume work as a lawyer. The London merchants at this time offered him £100,000 in recognition of his conduct, but Pitt replied that "No consideration on earth shall ever induce me to accept it." At the general election of 1790 he obtained an increased majority. In April 1791 by his Constitutional Act he arranged for the division of Canada into Upper and Lower Canada. The following year he accepted the wardenship of the Cinque Ports which carried a salary of £3,000 a year.

Foreign Policy.—The first important act of Pitt's foreign policy—the commercial treaty with France—was complementary to his reorganization of the home finances. The abandonment of useless trade restrictions was plainly to the benefit of both countries and Fox could think of no better ground of attack than to assert that France was the unalterable enemy of England, to which objection Pitt replied that "to suppose that any nation could be unalterably the enemy of another is weak and childish." In 1787 there was trouble in Holland. The Emperor Joseph II. had been for some time preparing a labyrinthine scheme whereby he should consolidate his dominions by annexing Bavaria, whose elector was to be compensated in the Austrian Netherlands. The scheme was agreeable to France who was intriguing for the overthrow of the Dutch stadholder and complete influence in Holland. War was only avoided after full preparations had been made (an expedition for instance was actually prepared for the capture of the Cape) because Prussia, who was opposed to Joseph II.'s policy was at length persuaded to stand with England. Upon Prussia's entry into Holland the Austro-Russo-French intrigue collapsed and the stadholder was restored. In 1789 England was brought into conflict with Spain who had seized the British trading post at Nootka Sound. Again war seemed imminent (over two millions sterling were spent in naval preparations), but Spain, receiving no support in Europe, was obliged to withdraw. Less successful was Pitt's intervention in the Eastern question. Catherine II. of Russia was at war with Sweden and Turkey. The Triple Alliance (of England, Prussia and Holland) had gained a prestige which placed it in a position to work for the maintenance of the balance of power. But though Austria's support was detached from Russia and Gustavus III. made peace with Catherine, the empress was not to be diverted from her ambitions in Eastern Europe. She gained great success in 1791, and Pitt, without adequate means of supporting his policy, determined to prevent Russia from establishing her power in the Black sea. He demanded that Russia should give up Oczakov, but Oczakov meant nothing on earth to the British public, and Catherine perceiving there was no force behind the ultimatum was unmoved by it. Though armament credits had been voted, Pitt was obliged to retire.

Pitt had not at first anticipated that the French Revolution would involve England in hostilities. In the spring of 1792 he was happily discussing finance, prophesying the reduction of 25 millions of debt in the next 15 years, and declaring in support of his vision that "there never was a time when, from the situation of Europe, we might more reasonably expect 15 years of peace than we may at the present moment." He had no intention of interfering in a matter which concerned France alone, and indeed in its original conception he was not unsympathetic to the aims of the Revolution. On Aug. 10th, the French monarchy fell, and the English ambassador was recalled from Paris, and Chauvelin in London could henceforward be only received unofficially. But this was merely a question of diplomatic routine: friendly relations were not strained until the French, having already declared war upon Austria and Prussia, followed the victory of Jemappes by occupying the Austrian Netherlands, threatening Holland, and overturning the treaties which governed the navigation of the Scheldt. England was bound by treaty to support Holland; and, as she had been through the centuries, she was not less insistently bound in this matter by her own interests. The execution of the king, and among the French people a rising tide of truculence swiftly fol-

lowed. On Feb. 1, while Pitt was outlining the provocations which Britain had received from France that country was despatching yet another in the shape of a declaration of war. The remainder of Pitt's life was to be spent in the shade of the revolutionary wars.

War.—The history of the wars with France is discussed under FRENCH REVOLUTIONARY WARS, NAPOLEONIC CAMPAIGNS, NAPOLEON; FRANCE, etc. It is only possible here to estimate generally the part that Pitt played in the organization of Europe. It has long been a current *cliché* to say that Pitt was a great peace minister and a poor war minister. But if Pitt's talents were indeed essentially suited to peace, it is equally true that Napoleon was finally encompassed in disaster by the dogged determination of the English premier, and after his death by the remembered influence of that resolution. To compare him with his father is idle; Chatham had every advantage. His allies were great commanders, his France was effete. But revolutionary France was inspired with a fanatic hope, and England's continental allies proved continually worthless. Year after year Pitt laboured to sustain his coalitions of the Powers; year after year the coalitions melted away before the victorious advances of the French. England, who had no call to be anything but a member of a general European league against France was forced to be the inspiration as well financially as politically of the entire organization.

Home Policy.—At home the war changed entirely the tranquil prospects of national wealth and prosperity. New voices were in the air—voices of political discontent, and shortly the voices too of hunger. Pitt's policy at home at this juncture is of great importance. Because he never again brought forward the question of reform after his failure in 1785, and opposed it whenever it was proposed by others, his sincerity has been openly called in question. His actions certainly demand some explanation. It is in the first place important to admit that there was as yet no national enthusiasm for reform: the cry had been raised largely in protest against the unconstitutional behaviour of the king, and had been lulled since the declaration of peace; moreover those who had been foremost in urging "economical reform" had no such belief in the necessity of parliamentary reform. A statesman—especially one on whom practically the whole conduct of a Government devolves—can not persist in a measure which has been again and again rejected in one form or another. Pitt had a large majority. But the fact that he remained in office for so long has obscured the truth that he was to a very large extent dependent upon the caprices of that majority. A contemporary political estimate recorded the number of those gentlemen who "would probably support his majesty's Government"—roughly the Court Party—as more than three times the size of Pitt's personal party: and there was a further shifting and entirely independent vote. For all his dominance of the House Pitt was sometimes defeated—over the Westminster petition (*see* Fox, CHARLES JAMES), over Ireland, over his proposals in 1786 to fortify Plymouth and Portsmouth. The demand for reform was not seriously supported in the House of Commons. More important still it was not as yet properly vocal outside its walls.

In 1792 Tom Paine's *Rights of Man* had been published, suddenly jolting the English Radical movement into a new mind at the moment when the French doctrines were filtering into England in a fashion admittedly designed to provoke dissensions. The circumstances had become altered. Pitt's refusal to support the motion for the repeal of the Test and Corporation Acts in 1789 and 1790 was unintelligibly craven; but when he refused to support Grey in 1792 he had excuse. "The hurricane season" had set in. Pitt allowed himself to be stampeded by a species of panic which was entirely unjustified by the facts. Talleyrand at this time remarked that those curiously deceived themselves who believed that England was on the verge of revolution. He was a more shrewd observer of truth—but it must be admitted that he had the advantage of looking at Britain not only in perspective but also dispassionately. Deceived or not, Pitt declared that this was no time to revise a constitution, and proceeded to punish severely any who should advocate reform doctrines. It was lamentable; it was essentially unjust; and there is but one excuse—the excuse which in sympathy has condoned many shameful

persecutions, when things are done in panic which are never justified by the patent facts but are believed to be necessary for profound reasons of State that can only be guessed at.

In 1793, and again in 1795–1801 *Habeas Corpus* was suspended, and bills for the suppression of sedition followed. There succeeded the trials and transportations of men like Skirving, Margatot, Gerrald, Muir, condemned for nothing more treasonable than advocating parliamentary reform or universal suffrage. Societies for constitutional reform were raided and suppressed. It is unpleasant to find that the records of the confiscated papers of those clubs reveal without exception nothing indicative of revolutionary organization. And yet in 1795 Pitt declared that were he to resign he would lose his head within six months. The circumstances were extraordinary, and it is just to suppose that Pitt was honest: he was not the less grievously wrong.

It was not long before the pain of war was felt in England. Pitt had based his confidence in a short period of war upon the pathetic belief that France would be financially incapable of sustaining a prolonged struggle. But the war advanced, and Pitt's subsidies were swallowed up upon the Continent by allies who made little or no return for them. The nation's debt mounted. The coalition crumbled. More money to buy more allies was needed. In 1795 after a season of bad harvests Pitt had to ask for a loan of 18 millions, and to increase the general taxation. Shortly afterwards followed the legacy duties. In 1797 taxation was increased by two millions; the next year produced the income tax.

Ireland.—One of Pitt's major pre-occupations was still Ireland. He had failed in 1785, but he never ceased to plan for the final consummation of his hopes. In 1793 Pitt forwarded the passage in the Irish House of Commons of the Catholic relief bill; but in 1794 he suffered disappointment when Irish opinion was again alienated by the position he was forced to adopt against the antics of Lord Fitzwilliam, who had been made lord lieutenant as a concession to the Portland Whigs who had entered the ministry in that year. Fitzwilliam and his party were anxious for a broad policy of reform and emancipation; but Pitt had laid down a cautious line of action, and it had been determined that Fitzwilliam should do nothing without the consent of the cabinet. But by "an open breach of a most solemn promise" he proceeded to dismiss the Irish Tory officials, and without authorization to promise widely the immediate prospect of a full emancipation. Fitzwilliam was recalled, and Ireland left to nurse an angry grievance. The whole bungling led directly to the disasters which followed; the state of semi-civil war in 1797 and the rebellion of 1798 and that disaffection which could welcome the French invasion. The union of Ireland and England which he had sought earlier for the mutual benefit of both countries was now imperative as a solution to a state of war. On Jan. 23, 1799, Pitt brought forward his proposals for a union of the two countries. Emancipation was not promised (the hostility of George III.'s eccentric conscience precluded the suggestion) but the hope was held out that this would follow in due course. The bill was pressed through the Irish parliament by Cornwallis, the viceroy, and Castlereagh, the secretary for Ireland. The distribution of titles and money played some part in this and more than a million pounds was expended in compensation to the holders of suppressed rotten boroughs. However open to moral criticism the latter decision may have been, it was essential to the support of the bill and it destroyed an entirely dishonest system of representation. As for the measure of the general corruption, that has at least been over-estimated, and in so far as material persuasion was adopted it must be remembered that bribery in the Irish parliament was a deeply respected tradition. Moreover it must have been patent to the guiding minds in Ireland that the present state of affairs was impossible, and the possible benefits of the union, for instance to trade, were obvious. The bill having passed the Irish parliament in 1800, the first united parliament met in Jan. 1801. Pitt had now to enlarge his policy, and once more the solution of Ireland's troubles was tragically postponed. Pitt had not promised emancipation, but those who had voted for the measure had been led to expect that it must follow. With a secrecy which

was perhaps unwise but understandable in the circumstances Pitt drew up his preliminary suggestions for the abolition of religious tests, the commutation of tithes, and provision for Catholic and dissenting clergy. The plan was opposed in the cabinet, principally by Lord Loughborough, the chancellor, who reported the matter to the king. George was enraged, and adamant against the proposals, and on Feb. 5 accepted the resignation which Pitt had tendered on Feb. 3. Immediately afterwards the situation was complicated by the king's relapse. During his temporary insanity, Pitt retained office until his recovery, finally resigning on March 14. Many bitter things were spoken of him. Once again he was accused of betraying his cause. But he had boldly brought forward his reforms, and his resignation followed upon their veto. Had he pressed his legislation, the king would have persisted inevitably in his opposition; moreover with the war going extremely ill it was not the moment to precipitate a domestic crisis. His promise to George never again to introduce the subject during the reign was sentimental, not necessary, and politically unwise. But he made it because the king had accused him of causing his illness and after all he might reasonably expect that the reign would be shortly finished. That Pitt intended to return to the fullest implications of his project is certain. But he himself had only five more years to live.

1801-1806

Retirement.—Henry Addington, who was called upon to lead the Government, had been universally praised as an expert speaker of the House of Commons; but he was no statesman. Pitt promised to do all he could to support Addington, and generously assisted in the conduct of negotiations for the Peace of Amiens. These terms which Grenville branded as "disgraceful and ruinous" appeared in general "highly satisfactory" to Pitt. Though he had long been anxious to conclude any peace which was at all reasonable, it is difficult to justify him in supporting a peace which recognized the failure of the coalitions to establish the independence of the Netherlands—which had been the ostensible *casus belli*. On the other hand there is evidence that Pitt was conscious of the unstable nature of the peace, and foresaw that a greater struggle was probable. The public supported the peace; and during the discussions a severe vote of censure upon Pitt was rejected, and a counter motion passed by 211 to 52 declaring that he had "rendered great and important services to his country, and deserves the thanks of the house." He retired now from parliament for the space of about a year, living largely at Walmer Castle, where as warden of the Cinque Ports he organized with great diligence and enthusiasm a local volunteer force. The brief interval gave an opportunity too for the examination of his debts. Pitt who had been so astute in public economy was careless of his own. He who had scornfully demanded an explanation of Lord North's expenditure of £340 of public money on whiccord, had himself to account for the grotesque item of £600 for hats. Both thoughtless and generous, Pitt was the victim of swindlers, and in 1800 already owed £45,000 despite the fact that he had received a salary of over £10,000 for many years. He nevertheless refused an offer of £100,000 from the citizens of London, and a gift of £30,000 from the king, though he accepted £11,700 as a loan from a committee of private friends; he was obliged to sell his house Holland.

Addington had won a great victory at the general election, but it was not long before his policy began to drift towards perilous courses. When it was clear that a rupture of the peace was imminent, Pitt was approached, but he no longer felt that Addington's policy could receive his honest support; and later negotiations provoked so wide and insistent divergencies of mind upon the personnel of a possible cabinet as to make agreement impossible and even to interrupt an ancient friendship. War broke out again on May 16, 1803. Against the insufficient programme of the ministry Pitt opposed a vigorous policy in a speech (May 23) which provoked the enthusiasm of all parties. But while the cleavage was growing plainer and plainer Pitt yet refused directly to oppose Addington, to whom he had promised his support. The situation was becoming increasingly serious. In the face of the

growing danger of invasion the measures of the Government were entirely inadequate, and early in 1804 Pitt was forced into stronger opposition. Complicated once again by a threatened relapse of the king, negotiations for a stronger administration were protracted. The ministry was doomed when a motion of Fox's for a committee of inquiry into the national defenses was powerfully supported by Pitt, and after some days of negotiation he returned as chancellor of the exchequer and first lord of the treasury on May 10.

Second Ministry.—Pitt's second term of office was marked by no great enterprises of governance. The war alone absorbed his energies. The labour and the inspiration of the great European coalition again rested exclusively upon Pitt, and his health, now gravely undermined, was beginning to break beneath the strain when early in April 1805 he suffered the pain of witnessing the public disgrace of his old friend and colleague Dundas (Lord Melville, *q.v.*). The battle of Trafalgar (Oct. 21) destroyed the possibility of invasion; but the year closed in disaster. The capitulation of Ulm (Oct. 20) was succeeded by Austerlitz (Dec. 2). At first Pitt was able to doubt the full implications of the news; but gradually, as dispatches authenticated the reports, he came to realize that the mighty coalition was hopelessly broken. England had saved itself by its exertions, he had remarked at the lord mayor's banquet in the previous November; it would save Europe by its example. And now Napoleon stood without a force to oppose him upon the whole continent; and Pitt, with prophetic accuracy, was brought to the bitter admission that the map of Europe would "not be wanted these ten years." On Jan. 23, 1806, he died, and if his last words were not "My country! How I leave my country!" his thoughts can have been none other.

Constitutional Importance.—The period of Pitt's government covered a supremely important moment of political transition. It was also a period of a not less important crystallization of British constitutional doctrine. It would be wrong to attribute that growth too strongly to Pitt's political acumen. Both the length and the critical instant of his ministry made development natural and inevitable. He was placed in the position of leadership at precisely the tactical moment. The fruit was ripe, but it was the harvest of a century of other men's labours. Pitt was the first Hanoverian minister to appeal definitely from the vote of the House of Commons to the vote of the constituencies, and throughout his career his strength was derived from the public confidence. In his colleagues Pitt appeared to prefer industry to genius. If this was partly because of an exaggerated sense of his own authority, it must also be remembered that the choice was also one of necessity. Pitt did overshadow his colleagues—but it was no difficult task. The result contributed to his general theory that the independence of Government departments was impossible. They must rather be bound together with a corporate policy, responsible to the Crown under a common allegiance to the prime minister. Walpole, who is generally considered the first prime minister, denied the title, and was succeeded by Governments which could only exist under the leadership of duumvirates and triumvirates. Pitt not only claimed the title of prime minister but declared that the office was essential to sane government. In 1803, when negotiations were on foot for a ministry in which the authority should be shared by himself and Addington, he stated that it was "an absolute necessity that there should be an avowed and real minister, possessing the Chief Weight in the Council and the principal place in the confidence of the King; in that respect there can be no rivalry or division of power. It must rest in the person generally called *first minister*, who ought to be at the head of the finances." And if a difference of opinion arose "the sentiments of the minister must be understood to prevail." This view moreover was widely understood by contemporary commentators. In 1794 when Lord Fitzwilliam went to Ireland he was pledged to support the Government "considering Mr. Pitt as the *Prime Minister* without whom no material measure as to *Things* or *persons* is to be concerted or done" (*Carlisle Papers*); and the Glenbervie diary (Dec. 30, 1798) corroborates this language. In everything Pitt laboured to assert the authority of the cabinet, and of the premier within the cabinet. He was the king's

minister; but not the minister of the king's policy. The theory was thrashed out over small details. Pitt claimed, for instance, that the Crown must follow his recommendations in the nominations of bishops, and when the king refused to concur declared that he would take it as a decisive mark of lack of confidence.

Cold, aloof, and sarcastic, supporting a reputation for an almost tiresome integrity, Pitt was not popular except, at a distance, with the people, who saw him as an inspired leader, or with his few intimates, who found him secretly gentle and affectionate. In perspective he has become a man of no little mystery and of unexpected inconsistencies. There seems no good enough reason adequately to explain his changed attitude towards Reform; his treatment of the Reform agitators; his cold indifference to social suffering in England; his support of the Addington ministry in spite of his patent disapproval of its conduct; the lack of a firmer policy during the Fitzwilliam fiasco in Ireland. He remains a statesman: indisputably supreme in debate and tactics and tireless in organization. Because of the failure of the allied cause in the war, it was once popular to assume that Pitt neglected the army and navy, depending solely upon his efforts as an international financier. The assumption is entirely unfair. British naval prestige was at a low ebb at the end of the American war, and it was largely owing to Pitt's interest and to his generous allocations of money that the administration was reformed, and the mastery of the sea re-captured. When Pitt entered office English credit was debased: restoration was effected by his regenerated understanding of finance. In 1783 England was practically outside the concert of Europe, yet in a few years she had become the director of an almost united European policy. A true perception of the future of the Empire was not to come before the 19th century. Yet Pitt's colonial interests were remarkably wide—covering not only the great administrative acts for India and Canada but also the colonization of Australia; the fortification of the West Indies; the defence of Nootka Sound. African settlements were considered, and the territories annexed during the war selected with remarkable discretion.

Actually and theoretically Pitt bridged the distance between the 18th and 19th centuries. He was the source of the emancipation of trade and finance from antiquated restrictions. He was the origin of modern financial theory. Yet, though he warmly supported the abolition of the slave trade, he did nothing to improve the condition of the worker, nothing to promote social emancipation at home. That is perhaps the measure of his position in history. He is revered but not loved.

Pitt was never married. He once professed a tender inclination towards the daughter of Lord Auckland; but the embarrassment of his debts prevented him from a formal declaration of his feelings. His real passion was for his work; and to that he gave his life.

BIBLIOGRAPHY.—The article in the Dictionary of National Biography contains a full bibliography. See especially Lord Rosebery's *William Pitt* and the works of Prof. J. H. Rose: *William Pitt and National Revival*, and *William Pitt and the Great War*; *Pitt and Napoleon*; and *A Short Life of William Pitt*. See also P. W. Wilson, *William Pitt, the Younger* (1930).

PITTA, a genus of birds remarkable for their great beauty of coloration. For a long while the pittas were commonly supposed to be allied to the *Turdidae*, but they form a separate family, *Pittidae* of the *Passeres*. There are about 50 species, divided into a number of genera, confined to the Old World, and ranging from India and North China to Australia, New Guinea and New Britain, with one species in West Africa, the greatest number being found in Borneo and Sumatra. Pittas vary in size from that of a jay to that of a lark, and have a strong bill, a thick-set form, which is mounted on rather high legs with scutellated "tarsi," and a very short tail. In many of the forms there is little external difference between the sexes.

PITTACUS, of Mytilene in Lesbos (650?–570 B.C.), one of the Seven Sages of Greece. About 611, with the assistance of the brothers of the poet Alcaeus, he overthrew Melanchrus, tyrant of Lesbos. In a war (606) between the Mytilenaeans and Athenians for the possession of Sigeum on the Hellespont he slew the

Athenian commander Phrynon in single combat. In 589 his fellow citizens entrusted Pittacus with despotic power (with the title of Aesymnetes) for the purpose of protecting them against the exiled nobles. He resigned the government after holding it for ten years. According to Diogenes Laërtius, who credits him with an undoubtedly spurious letter to Croesus, Pittacus was a writer of elegiac poems, from which he quotes five lines.

See Herodotus v. 27, 94; Diog. Laërt. i. 4; Lucian, *Macrobius*, 18; Strabo xiii. 600, 617–618; Aristotle, *Politics*, ii. 12, iii. 14; T. Bergk, *Poetae lyrici graeci*.

PITTSOPORUM, the most numerous genus of the family Pittosporaceae, comprising about 100 species of evergreen trees and shrubs, native to tropical regions of the Old World, chiefly in the Southern Hemisphere.

Many species are grown as ornamentals in warm regions, as in Florida and California, and as house or greenhouse plants in cooler latitudes. *P. tobira* (Japanese pittosporum) and *P. viridiflorum* (Cape pittosporum) are attractive winter-blooming shrubs; *P. rhombifolium* (Queensland pittosporum) is often planted for avenues; *P. undulatum* (Victorian box), of Australia, is suitable for pruned hedges; *P. eugenioides* (tarata), of New Zealand, is useful in shrubberies; and *P. crassifolium* (karo) is planted for seaside windbreaks.

PITT-RIVERS, AUGUSTUS HENRY LANE-FOX (1827–1900), English soldier and archaeologist, son of W. A. Lane-Fox, was born on April 14, 1827. He entered the army, served in the Crimean War, and was one of the founders of the Hythe School of Musketry. General Pitt-Rivers made a collection of weapons and other things which was presented in 1883 to the University of Oxford. When, in 1880, General Pitt-Rivers obtained possession of his great-uncle's estates—practically untouched by the excavator since they had been the battleground of the West Saxons, the Romans and the Britons—he devoted himself to exploring them. His excavations round Rushmore resulted in valuable "finds"; he founded a local museum and published several illustrated volumes. As a scientific archaeologist he attained high rank. He received various honours, including the F.R.S. He married, in 1853, Alice Margaret, daughter of the second Lord Stanley of Alderley; and was the father of a large family; his second daughter became in 1884 the wife of Sir John Lubbock (Lord Avebury). He died at Rushmore on May 4, 1900.

PITTSBURG, a city of Contra Costa county, Calif., U.S., served by the Santa Fe, the Southern Pacific, the Western Pacific railways and by steamship lines. The population of Pittsburg was 12,662 in 1950. It has large steelworks, a furniture plant, planing mills, shipyards and asbestos, rubber, firebrick and chemical factories. It was founded in 1835. Coal was discovered in 1863, and the town was incorporated as Black Diamond. In 1911 it was chartered as a city and the present name was adopted.

PITTSBURG, a city of Crawford county, Kan., U.S., on federal highways 69 and 160, near the southeast corner of the state. It is served by the Frisco, Kansas City Southern, Missouri Pacific, Santa Fe and Joplin-Pittsburg railways. Pop. 19,371 in 1950. It is in a bituminous coal field where 3,000,000 tons or more are mined annually, and is near oil and gas fields and the lead and zinc region of Kansas and Missouri. The main shops of the Kansas City Southern railway are there, and there are iron foundries, large pottery, sewer-pipe works and other manufacturing industries, with an aggregate output in 1949 valued at \$8,465,000. Bank clearings for 1949 amounted to \$132,632,000. The Kansas State Teachers college of Pittsburg (est. 1903) has an annual enrolment of more than 2,000. The city was chartered in 1876. By 1880 the population was 624.

PITTSBURGH, the second largest city of Pennsylvania, U.S., and the county seat of Allegheny county, on the Allegheny, Monongahela, and Ohio rivers (latitude 40° 28' N., longitude 80° W.). The rivers are normally 710 ft. above sea level and the highest point in the city is 1,365 ft. Annual average mean temperature is 52° F.; January 31° F. and July 74° F. Pop. (1910, after annexation of Allegheny) 533,905; (1920) 588,343; (1930) 669,817; (1940) 671,659; (1950) 673,763. In previous census years the population was as follows: (1800) 1,565; (1820) 7,248;

(1840) 21,115; (1860) 49,221; (1880) 156,389; (1890) 238,617; (1900) 321,616. Accretions of population and land area by annexation between 1930 and 1950 were of minor significance. As a city Pittsburgh ranked 12th in population in the United States at mid-20th century. The population of Allegheny county in 1950 was 1,508,255. The Pittsburgh metropolitan area had a population of 2,205,544; only one other U.S. city (Boston) had a smaller proportion of its population within its corporate limits. In distribution of population by race and country of birth, Pittsburgh is representative of national averages.

The land area of the city is 54.3 sq.mi. The chief business area, the "golden triangle," covers 974.3 ac. or 1.52 sq.mi.

Picturesque rolling plateaus, the three rivers and narrow valleys, from which rise high hills or precipitous bluffs, are the principal natural features of the district. Department stores, banks, tall office buildings, hotels, theatres and railway terminals are concentrated in the triangle, formed by the confluence of the Allegheny and Monongahela, with Fifth avenue as the principal thoroughfare. Factories extend for several miles along the river banks and into the tributary valleys.

Rugged topography, which affords the city a spectacular setting, imposes difficulties in communication which have been ingeniously surmounted. More than 200 bridges span the valleys within the city's limits. Inclined railways carry passengers to hills overlooking the business centre. Twin tunnels (each tube 25 ft. wide and 5,889 ft. long) under Mt. Washington connect southern residential areas with the city by a high-level bridge over the Monongahela. In 1951 construction was far advanced on a high-speed parkway to carry traffic from highway routes 22 and 30 to the edge of the business district and thence, by a new bridge and tunnel, westward. Mass transportation is provided chiefly by electric street railways, supplemented by motor coaches.

Following a long-range, large-scale development of flood control (reservoirs in the headwaters of the two rivers by 1951 were scheduled to reduce the level of floods at Pittsburgh by 10.1 ft.), a vast program of improvements in the downtown business district was undertaken by local and state governments and private enterprise, chiefly stimulated by the Allegheny Conference on Community Development, a citizens' planning and co-ordinating group. Demolition of buildings and street relocations on 59 ac. at the apex of the triangle was far advanced in 1950. On 36 ac. was to be created a park and traffic interchange on the site of Forts Duquesne and Pitt. On 23 ac., cleared by the Pittsburgh Redevelopment authority, ground was broken in 1950 for three 20-story office buildings, to be followed by others, in a planned large-scale development in a parklike setting. Elsewhere in the triangle the Pittsburgh Parking authority had acquired sites for the first four major parking garages in a program contemplating accommodations for 22,000 cars. One of these sites, for sub-surface car storage under a park, comprises a city block in the heart of the business district, the acquisition of which was made possible by gifts totalling \$4,000,000 to the city of Pittsburgh by three foundations established by members of the Mellon family. A 40-story office building, to be shared by the Mellon National Bank and Trust company and the U.S. Steel corporation, and a 30-story building for the Aluminum Company of America were under construction in 1951. Among other major buildings in the district are the Frick, Oliver, Union Trust, Koppers, Gulf, Grant, Farmers and First National Bank. Notable governmental buildings are the City-County, U.S. post office and the Allegheny county courthouse (1884), widely known as one of H. H. Richardson's masterpieces.

Educational and Cultural Institutions.—In 1950 there were 20 public high schools, junior and senior, with 906 teachers and 23,648 pupils, 6 vocational schools with 120 teachers and 3,071 pupils and 97 elementary schools with 1,129 teachers and 37,404 pupils. There were also 94 kindergartens and 12 veterans' vocational units. In evening classes were 17,847 pupils. Catholic parochial schools in the city had 25 high schools with 319 teachers and 7,008 pupils and 84 elementary schools with 931 teachers and 36,196 pupils.

The city has three universities and two colleges for women with

a total enrolment of 37,869 and 2,967 instructors in 1950. The University of Pittsburgh is widely known for its principal building, the 42-story "cathedral of learning," located at the main entrance to Schenley park. Partly state-supported, it had, in 1950, an \$8,600,000 endowment, 26,244 students and a faculty of 2,122. Carnegie Institute of Technology, also adjoining Schenley park, had a \$29,000,000 endowment, 5,214 students and a faculty of 408. Duquesne university, located near the business centre of the city, had 5,165 students and a faculty of 338. Mount Mercy college for women had 724 students and a faculty of 42. Pennsylvania College for Women had a \$2,250,000 endowment, 522 students and a faculty of 57. The city also has three theological seminaries: Western (Presbyterian, founded 1825) 100 students, 15 faculty; Pittsburgh-Xenia (United Presbyterian, founded 1825) 129 students, 11 faculty; and Reformed Presbyterian, (founded 1810) 13 students, 4 faculty. Among special schools are institutions for the education of the blind and deaf.

Following years of intensive development, Pittsburgh by mid-20th century had achieved an outstanding position among U.S. cities as a centre of research in the natural sciences. Notable programs were being conducted both at the University of Pittsburgh and at Carnegie Institute of Technology. The latter institution has large research laboratories in coal and metals and, in 1950, completed construction of a \$2,000,000 synchrocyclotron with a capacity of approximately 400,000,000 ev, one of the most powerful in the United States. Mellon institute, renowned as a centre for industrial research, and the laboratories of the U.S. bureau of mines are located in Pittsburgh. Important industrial research laboratories include those of the Gulf Oil corporation, Westinghouse Electric corporation, Aluminum Company of America, the Carnegie-Illinois and Jones & Laughlin Steel corporations, Pittsburgh Plate Glass company and Koppers company.

Outstanding among cultural institutions is Carnegie institute, established by Andrew Carnegie, its main building containing a library, a department of fine arts (known for its international exhibition of paintings), a museum and a music hall. The library, including its various branches, in 1950 had 1,193,000 volumes. The independent Carnegie Free Library of Allegheny was the first to be given to a city by Carnegie. Phipps conservatory, one of the finest in the United States, was presented to the city in 1903 by Henry Phipps. The Buhl planetarium was dedicated in 1939 in honor of Henry Buhl, Jr. The Pittsburgh symphony orchestra, the Civic Light Opera (open-air summer programs) and the Pittsburgh Playhouse are outstanding.

The city has 19 public parks, well-distributed, with a total area of 1,917 ac. Most of them are located on high, rolling land and several afford dramatic views of the industrial valleys below. Overlooking the Monongahela river is Schenley park (456 ac.), the first, of which about 400 ac. were given the city in 1890 by Mrs. Mary E. Schenley. Overlooking the Allegheny river is Highland park (425 ac.) which contains the principal city reservoirs and the municipal zoo. Also in the eastern portion of the city are Frick park (457 ac., mostly woodland), donated by Henry C. Frick, and Mellon park, the gift of Richard K. Mellon, where are located an arts and crafts centre and extensive recreational facilities. On high ground in the Allegheny or north side district is Riverview park (240 ac.) which contains the Allegheny observatory, once directed by Samuel Pierpont Langley. Supplementing these facilities are North and South parks (each 1,200 ac.), developed by Allegheny county.

Pittsburgh is the see of Roman Catholic and Protestant Episcopal bishops and the residence of a bishop of the Methodist Church. Among the fine churches of the city are St. Paul's cathedral, Calvary, Sacred Heart, Trinity cathedral (Episcopal), First Presbyterian, East Liberty Presbyterian (architect, Ralph Adams Cram), First Baptist and Heinz Memorial chapel (architect, Z. L. Klauder).

The city has one morning newspaper, the *Post-Gazette* (established as the *Pittsburgh Gazette* in 1786), and two evening papers, the *Press* (Scripps-Howard) and *Sun-Telegraph* (Hearst). A number of papers devoted to language and racial groups are also published, and the city is a centre of publication for trade journals.

THE "CIVIC CENTRE" OF PITTSBURGH

In the left centre is the University of Pittsburgh's 42-story Gothic "cathedral of learning," with the Stephen C. Foster memorial immediately in front. To the right of the "cathedral" is the Heinz Memorial chapel and the Mellon Institute (with colonnade). At the upper left is the university's "upper campus," including Pitt stadium, the medical centre and the professional schools. In the lower left is the Carnegie library and museum

COMMERCE AND INDUSTRY IN PITTSBURGH

1. The compact business district of Pittsburgh known as the Golden Triangle. It is formed by the Allegheny river (right) and the Monon-

gahela river (left) where they meet to form the Ohio river
2. Night view of the Pittsburgh steel mills

Pittsburgh pioneered in the development of radio, and KDKA was the world's first broadcasting station.

Public Health, Housing and Welfare.—Smoke control legislation, effective in Pittsburgh in 1947 and subsequently extended to Allegheny county, drastically decreased air pollution and was hailed as the most notable health advance since the establishment of filtration for water supplies. In 1951 engineering plans were far advanced on design for a \$60,000,000 sewage treatment plant to serve Pittsburgh and nearly 60 other communities. Support of programs of public health received impetus from a \$13,600,000 gift (1948) by the A. W. Mellon Educational and Charitable trust to establish a graduate school of public health at the University of Pittsburgh. The medical school of the university in 1950 had 338 students and the school of dentistry 371. The city in 1950 had 24 hospitals with a total bed capacity of 6,273. In municipalities of Allegheny county outside of Pittsburgh were eight other hospitals with a total bed capacity of 1,265. Three veterans' hospitals (including two under construction in the city in 1950) had 3,000 beds.

Because of its rugged topography Pittsburgh ranks relatively low among U.S. cities in population per gross acre, although on buildable residential areas it is compact. The city is traditionally one of single-family residences and ranks high in percentage of home ownership. After 1945, however, there was a marked increase in apartment house building. Pittsburgh's best-known residential district is Chatham Village, pioneer large-scale, planned community, built (1932-36) as a demonstration by the Buhl foundation. The Housing authority of the city (est. 1937) managed seven public housing projects at mid-century, containing 5,462 family units.

The tradition of private philanthropy is deeply rooted in Pittsburgh. The Health and Welfare federation in 1950 had 181 member agencies and the community chest conducted joint financing for 92 agencies. Schools of social work are conducted at the University of Pittsburgh and Carnegie Institute of Technology.

Public trusts of general philanthropic purposes had assets with a market value of more than \$100,000,000. Of these the largest were the A. W. Mellon Educational and Charitable trust, \$44,000,000; Buhl foundation, \$13,000,000; R. K. Mellon foundation, \$11,000,000; Maurice and Laura Falk foundation, \$9,300,000; and Sarah Mellon Scaife foundation, \$6,500,000. The W. L. and May T. Mellon foundation concluded its program in 1949 with a \$6,000,000 grant to establish a graduate school of industrial administration at Carnegie Institute of Technology. Trusts of more specialized purposes include the Carnegie Hero fund, \$9,700,000, and the Henry Clay Frick Educational commission, \$2,300,000.

The Pittsburgh foundation (\$2,500,000), a community trust, was established in 1945.

Transportation, Industry and Finance.—Known in the days of settlement and expansion as the "gateway to the west," Pittsburgh is one of the nation's leading centres of transportation. Rivers, rails, highways and airports carry an impressive tonnage. Dams and locks in the Monongahela and Allegheny rivers provide a minimum pool depth of nine feet to Fairmont, W. Va., 128 mi. to the south, and to East Brady, Pa., 72 mi. to the north. The Ohio river connects this system with the Mississippi and the Gulf of Mexico. The shore line of the Pittsburgh harbour extends 48.2 mi., of which 30.4 mi. are within the city. Pittsburgh is a port of entry. Total river tonnage in the Pittsburgh engineering district in 1948 was 38,400,000. Five major rail trunk lines and a score of switching or terminal lines serve Pittsburgh. Trunk lines are the Pennsylvania, the New York Central (Pittsburgh and Lake Erie), the Baltimore and Ohio, the Buffalo, Rochester and Pittsburgh, the Bessemer and Lake Erie and the Pittsburgh and West Virginia. The total rail tonnage for the Pittsburgh rate zone in 1948 was 134,655,000. Two major airports serve Pittsburgh. One of them covers 1,600 ac. and ranks among the five largest in the United States. All American, Capital, Eastern, Northwest and Trans World air lines serve Pittsburgh. As the centre of major highways from east to west and from north to south, the city is an important centre of motor freight transporta-

tion and of tourist travel. It is served by the Pennsylvania turnpike, a four-lane, high-speed, state-built toll road extending from Philadelphia to the Ohio line.

Pittsburgh's industrial importance is based upon western Pennsylvania's rich natural resources, particularly of coal, petroleum and natural gas. Allegheny county alone in 1948 produced 16,214,000 tons of coal. The city's favourable location with respect to the great iron ore deposits on the Great Lakes gave it early dominance in the steel industry and, despite the rise of large steel-producing centres elsewhere, midway in the 20th century Allegheny county produced more than one-seventh of the national total of ingot tonnage. Diversification of heavy industrial production proceeded at an accelerated pace immediately before and after World War II. The district is important in steel fabricating and in machinery manufacture, particularly of mill machinery and electrical goods. Here are located the plants of some of the largest subsidiaries of the U.S. Steel corporation as well as the Jones & Laughlin company and other important independent producers. It is the home of three widely known companies established upon the inventive genius of George Westinghouse—the Westinghouse Electric corporation, the Westinghouse Air Brake company and the Union Switch and Signal company. The city is the seat of the Aluminum Company of America, which has one of its largest fabricating plants in the region, and of the Gulf Oil corporation. It has a major plant and is the home of one of the world's best-known food processors, the H. J. Heinz company. Allegheny county in 1948 had 559,000 persons gainfully employed.

Pittsburgh is notable for the strength of its banking structure. Twenty-nine banks, at the beginning of 1950, had deposits totalling \$2,277,000,000, and bank clearings in the preceding year totalled \$14,750,000,000.

Government.—Pittsburgh's sesquicentennial anniversary was observed in 1908. It was incorporated as a borough in 1794 and as a city in 1816. By act of legislature (1911) the government was put in the hands of a mayor and a council of nine members, elected at large by popular vote, for four-year terms, and eligible for re-election. The mayor appoints department heads and members of various commissions, including civil service, sinking fund, planning, better traffic and art, and the members of the Urban Redevelopment authority. The heads of the six chief service departments also are appointed by the mayor: safety, health, works, parks and recreation, supplies, and lands and buildings. The council is the legislative body. Within permissive state legislation, it determines the objects of taxation and fixes the rates, authorizes expenditures and contracts, fixes salaries of city employees and may approve or disapprove appointment of department heads by the mayor. The mayor has power of veto over bills passed by council which, in turn, may override him by a two-thirds vote. The cost of city government in 1949 was \$33,500,000. The chief source of city revenue is a tax on real estate, the rate on land being twice that on buildings. Mercantile, personal property and amusement taxes are also levied.

The school district of the city of Pittsburgh, although co-terminous with the municipality, is a distinct entity of government. The board of public education is composed of 15 members, non-salaried, appointed by the judges of the common pleas court of Allegheny county for six-year terms. Administration is through two departments: education, headed by the superintendent of schools appointed by the board for a four-year term; and business, headed by a manager appointed annually. The cost of operation in the school district in 1950 was \$19,000,000. The chief source of school revenue is the tax on real estate, supplemented by mercantile, per capita and personal property taxes; approximately one-eighth of the cost is provided by state subsidy.

Taxable real estate in 1950 in Pittsburgh was \$981,082,764; in Allegheny county, \$2,067,000,000.

For the history of Pittsburgh *see* PENNSYLVANIA. (C. F. Ls.)

PITTSFIELD, a city of western Massachusetts, U.S., the county seat of Berkshire county; on federal highways 7 and 20, and served by the Boston and Albany and the New York, New Haven and Hartford railways.

The population in 1950 was 53,348; 1940, 49,684 by federal

census. It occupies 42.4 sq.mi., at an altitude of 1,000 ft., in the midst of the Berkshire hills. Three branches of the Housatonic river wind through the city, uniting about a mile from the central green. Within its limits are the whole or parts of three lakes (Pontoosuc, Onota and Morewood). It is a touring centre and a resort for summer and winter sports. Its manufacturing industries include the world's largest electric transformer and plastic plants of the General Electric company; and the mill that makes all the paper used for the U.S. bank notes and government bonds. The oldest industry is textile manufacturing, chiefly woollen goods. Fine stationery, paper-mill equipment, machine tools, spool silks and silk braids are other leading products.

The first settlement within the present boundaries of Pittsfield (Boston Plantation or Pontoosuc), made in 1743, was soon abandoned because of trouble with the Indians. It was revived in 1749, and in 1761 was incorporated as the town of Pittsfield, named in honour of the elder William Pitt. The town was chartered as a city in 1891. Shaker Village was settled (by Shakers) about 1790.

Elkanah Watson (1758–1842), while living (1807–16) at what is now the country club, introduced the merino sheep. When he exhibited on the village green his sheep along with the livestock and produce of other farms, he became the father of the agricultural fair.

PITTSFORD, a city of Luzerne county, Pennsylvania, U.S., on the Susquehanna river, about midway between Scranton and Wilkes-Barre. It is served by the Central of New Jersey, the Delaware and Hudson, the Erie, the Lackawanna, the Lackawanna and Wyoming Valley and the Lehigh Valley railways. The population of Pittsford in 1950 was 15,012; in 1940 it was 17,828 by the federal census. Within a 2.5 mi. radius from the city hall is a population of more than 70,000.

Pittsford is the centre of the anthracite coal region. The city also has foundries, machine shops, textile mills, apparel factories, mine and railroad machine shops, and plants making food, shoes, springs, cables and tobacco products. It was one of the five towns founded in the Wyoming valley by the Susquehanna company of Connecticut, and was named after the elder William Pitt. It was founded about 1768 and chartered as a city in 1894.

PITUITARY BODY. The pituitary body (hypophysis cerebri) is an endocrine or ductless gland. Thus, its cells secrete their specific products, the pituitary hormones, directly into blood capillaries. The term hypophysis is derived from the Greek "lying under," descriptive of the gland's anatomical position under the brain. The pituitary plays an extremely important part in the normal functioning of the human body. Since its effects are largely mediated through its control over other endocrine glands, it is described as the "master gland" or "the conductor of the endocrine orchestra."

History.—The name pituitary was given to the gland by Andreas Vesalius (1514–64), who shared the belief advanced by Galen (c. A.D. 130–200) that it derived from the brain a mucous substance, pituita or phlegm, which it secreted into the nose and upper pharynx. Other early workers, including Franciscus Sylvius (1614–72) and Raymond Vieussens (1641–1716), considered that the structure played a part in the elaboration of cerebrospinal fluid, a viewpoint also expressed by Thomas Willis in 1664. Richard Lower in 1672 was probably the first to ascribe an endocrine role to the gland, for he considered that it removed fluid from the cerebrospinal fluid and secreted it into the blood stream, and not into the nasopharynx.

Modern investigations concerning the structure and function of the pituitary can be said to date from 1886 when the French neurologist Pierre Marie described an association between pituitary tumours and a form of gigantism. Then in 1894 the English investigators G. Oliver and E. A. Schafer demonstrated that pituitary extracts when injected intravenously caused an elevation of blood pressure. In 1896, the U.S. physiologist W. H. Howell showed the substance responsible for the pressor effect was present only in extracts of the posterior lobe of the gland, and in 1906 Sir Henry Dale observed that these extracts also caused contraction of the uterus. The U.S. neurosurgeon Harvey Cushing, in

the early part of the 20th century, successfully removed the pituitary from dogs and advanced the knowledge of the pituitary by both experimental and clinical studies that included surgical procedures for the removal of pituitary tumours in man. In 1921, H. M. Evans proved the anterior lobe of the pituitary contained a growth-promoting hormone and some 20 years later he and his associates at the University of California succeeded in isolating this hormone in pure form. Later researches were directed toward isolation and identification of the various hormones, the determination of the cells of origin of these various hormones, and the elucidation of the reciprocal relation of the pituitary and other endocrine glands.

Structure.—*Gross Anatomy and Embryology.*—The pituitary gland in the human adult weighs about 0.5 g. and measures about 1 cm. in length, 1.5 cm. in breadth and 0.6 cm. in depth. The pituitary of the whale weighs from 10 g. to 60 g.; of the beef, 2.5 g.; of the dog, 0.065 g. and of the cat 0.009 g. The gland is situated in a depression on the surface of the sphenoid bone. This depression, known as the *sella turcica* ("Turkish saddle"), is deep in some species, including man, and quite shallow in others. As is shown in the figure, the gland itself consists of two divisions: a

DIAGRAM OF A SAGITTAL SECTION THROUGH THE PITUITARY GLAND

neural division, the neurohypophysis, derived embryologically from the floor of the diencephalon and a glandular division, the adenohypophysis, derived from an outpouching of the roof of the mouth (Rathke's pouch). The neurohypophysis consists of three parts, the median eminence of the tuber cinereum, the infundibular stem and the infundibular process or neural lobe. An extension of the third ventricle penetrates the median eminence and in some species extends into the neural lobe. The adenohypophysis normally loses all connection with the roof of the mouth. In most species, the posterior portion of the developing adenohypophysis becomes so closely applied to the neural lobe that the two cannot be separated, and together form the posterior lobe. The portion of the posterior lobe derived from the adenohypophysis is known as the pars intermedia or intermediate lobe. It is frequently separated from the anterior lobe by the colloid-filled cleft. In certain animals such as the cetaceans, armadillo and beaver and in birds, a discrete intermediate lobe is missing and anterior and neural lobes are separated by a thin layer of connective tissue. A small portion of the adenohypophysis known as the pars tuberalis, extends up the infundibular stem and often encircles it.

Microscopic Structure.—The anterior lobe consists of branching cords of cells supported by a reticulum of connective tissue, and separated by wide vascular channels known as sinusoids. Based on staining properties, the cells are classified into chromophobes and chromophiles. These two cell types are present in almost equal numbers. The finely granular cytoplasm of the chromophobes has a poor affinity for the conventional stains. In about 75% of the chromophiles, the cytoplasm contains granules that are stainable with acidophilic dyes and the cells are known as acidophils, eosinophils or alpha cells. The remaining chromophiles contain granules which stain with basophilic dyes and the cells are known as basophils, cyanophils or beta cells. Chromo-

philes are situated close to the blood sinusoids and are thought to represent the actively secreting cells of the anterior lobe. Chromophobes tend to be present in the central portion of the cell cords and it is felt that they represent inactive stages. The intermediate lobe is less vascular than the anterior lobe and consists of cells whose cytoplasm stains faintly with basic dyes, as well as cells similar to the chromophobes of the anterior lobe. The pars tuberalis is more vascular than the intermediate lobe and consists of small cells with chromophobic or slightly basophilic nongranular cytoplasm. These cells are frequently arranged in the form of small follicles with a colloid-filled lumen.

The neural lobe resembles the gray matter of the brain rather than a typical endocrine gland in structure. The cells present in greatest numbers are the pituicytes. The neural lobe also contains numerous unmyelinated nerve fibres and a fairly rich blood supply. The nerve fibres originate from nerve cells situated in the hypothalamus (the supraoptic and paraventricular nuclei). The fibres sweep down the infundibular stalk and spread out to form a rich network in the lobe. A characteristic of the neurohypophysis is the large amount of intercellular substance which in the course of fixation precipitates into granules known as Herring bodies.

Blood Supply.—The pituitary receives arterial blood from the internal carotid and from the circle of Willis. There is also a venous portal system between the hypothalamus and the anterior pituitary. Venous drainage from the pituitary is into the cavernous sinus.

Nerve Supply.—The neurohypophysis is richly supplied with unmyelinated nerve fibres from the hypothalamic nuclei. It is questionable whether any of these enter the anterior lobe which does receive some sympathetic fibres from the carotid plexus and parasympathetic fibres from the greater superficial petrosal nerves, themselves branches of the facial nerve.

Hormones of the Pituitary Gland.—*Anterior Lobe.*—By the late 1950s six hormones were isolated from the adenohypophysis and the existence of a number of others was postulated. The identified hormones all appeared to be protein or polypeptide in nature and some were isolated in pure form. It was shown that a hormone from one species may be chemically different from that derived from another species. This may explain the occasional failure of a hormone to elicit an effect in a different species. Thus the fact that human and beef growth hormones differ chemically may account for the apparent ineffectiveness of growth hormone prepared from beef when administered to man. Furthermore, species differences could lead to antibody formation (antihormones) which may account for the refractoriness that often develops after extended use of these preparations.

The growth hormone is necessary for normal growth. A type of dwarfism is caused by the absence of this hormone. Excessive growth hormone production results in gigantism in children and acromegaly in adults. The effect of the hormone appears to be a direct one on the tissues of the body. Prolonged administration to certain species results in the development of diabetes, an effect formerly thought to be due to a separate diabetogenic principle. The thyrotropic hormone (thyrotropin; TSH) stimulates the growth of the thyroid gland and the secretion of the thyroid hormone. In its absence, myxoedema may develop, indistinguishable clinically from the true myxoedema (*g.v.*) due to a primary underactivity of the thyroid gland. In the 1950s some investigators felt that exophthalmos (pathological prominence of the eyes) may be the result of excessive pituitary stimulation and that thyrotropin or a closely related substance is responsible for the condition.

The adrenocorticotrophic hormone (corticotropin; ACTH) stimulates the growth of the adrenal cortex and the release of its hormones. In its absence, signs of adrenal insufficiency (Addison's disease) develop. The follicle-stimulating hormone (FSH), the luteinizing hormone (LH) and the lactogenic hormone (prolactin) are sometimes classed together as the gonadotropic hormones. The follicle-stimulating hormone promotes growth of ovarian follicles in the female and stimulates spermatogenesis in the male. The luteinizing hormone stimulates the formation of the corpus luteum from follicles which have ripened under the influence of the follicle-stimulating hormone. The lactogenic hormone causes secretion of milk by mammary glands adequately developed under the influence of the ovarian hormones.

Intermediate Lobe.—The intermediate lobe produces the melanophore-expanding hormone (intermedin) which causes darkening in frogs and certain other lower vertebrates, due to a dispersal of pigment in the pigment-bearing cells (chromatophores). In animals in which there is no anatomically distinct intermediate lobe, intermedin is found in the anterior lobe. In the lower vertebrates, the alterations in colour scheme effected by intermedin serve as a protective mechanism, permitting the animal to blend with his surroundings and thus to escape detection. It was not established by the latter 1950s whether intermedin plays a role in higher vertebrates. Chemical studies revealed that intermedin and the adrenocorticotrophic hormone are remarkably similar in chemical structure and led some investigators to believe that they may actually be identical.

Neural Lobe.—In 1928 O. Kamm and his associates separated pos-

terior pituitary extracts into two partially purified fractions, oxytocin (Pitocin), which elicited largely oxytocic activity, and vasopressin (Pitressin) which contained largely blood-pressure raising and anti-diuretic activities. In 1953, these substances were isolated, identified and subsequently synthesized by Vincent du Vigneaud, who was awarded a Nobel prize in chemistry in 1955 in recognition of this work. Both vasopressin and oxytocin are polypeptides, consisting of eight amino acids each. Vasopressin, whether natural or synthetic, causes an elevation of blood pressure through a direct action upon the smooth muscles of the blood vessels and has an antidiuretic action effected by increased absorption of water by the kidney. Vasopressin also has a stimulating action on the gastrointestinal tract and a slight oxytocic activity. Oxytocin on the other hand causes contraction of the uterus, a fall of blood pressure in birds and an outpouring of milk from the breasts of lactating animals. It also has very slight pressor and anti-diuretic activities. The synthesis of vasopressin and oxytocin led to the virtual abandonment of the theory at one time fairly widely held that the pressor and antidiuretic activities of neural lobe extracts were elicited by separate hormones.

As of the mid-1950s it remained a matter of some dispute as to which of the various pharmacodynamic actions of neural lobe extracts are of a hormonal nature. It was generally held that the antidiuretic effect, elicited by minute traces of vasopressin, plays an important role in maintenance of water balance and it appeared probable that oxytocin is responsible for the "let-down" of milk; *i.e.*, the release of milk from the lactating gland initiated by the act of suckling. It was not established, however, by the mid-1950s, that oxytocin is of physiologic importance in parturition, or that vasopressin plays a role in the regulation of blood pressure.

Considerable controversy surrounded the question as to whether vasopressin and oxytocin exist in the gland as separate entities or whether they are split off from some larger protein molecule in the process of chemical isolation procedures. The latter hypothesis was first advanced by J. J. Abel in 1920 and was supported by the isolation by H. B. van Dyke in 1942 of a purified protein, containing pressor, oxytocic and antidiuretic activities in the same proportions in which they are present in the gland. On the other hand the pressor-oxytocic ratio is not constant in all species; furthermore, certain stimuli seem able to release one activity only. These findings, however, would still be consistent with the view with the active principle is elaborated as one large protein from which the active polypeptides may be split off and either stored or released according to the body's needs.

Cellular Origin of Pituitary Hormones.—*Adenohypophysis.*—The number of hormones isolated from the anterior hypophysis exceeds the number of distinct cell types; hence it was presumed that a single cell type may give rise to more than one hormone. As of the mid-1950s growth hormone was thought to be secreted by the alpha cells. Tumours composed largely of alpha cells were demonstrated in acromegaly and pituitary gigantism. Furthermore, in a hereditary strain of dwarf mice alpha cells are lacking. Gonadotropic hormones were thought to arise from beta cells. Thus, castration results in typical changes in these cells, the cells becoming more numerous, enlarged and vacuolated (castration cells). The beta cells also seemed to be responsible for the secretion of the thyrotropic and adrenocorticotrophic hormones, though the evidence was not too clear cut with respect to the adrenocorticotrophic hormone.

Intermedin is undoubtedly secreted by the cells of the pars intermedia. The distribution of intermedin-secreting cells was not established, by the mid-1950s, in those species in which a discrete pars intermedia is lacking.

Neurohypophysis.—The site of secretion of the active principles of the neural lobe remained a matter of some controversy at mid-20th century. The early view was that the hormones were elaborated by the pars intermedia and diffused into the neural lobe to form the Herring bodies. This viewpoint was rendered untenable when it was shown by E. M. K. Geiling that an intermediate lobe is missing in certain species and that in these species, pressor and oxytocic activity are present only in neural lobe extracts and melanophore-expanding activity only in anterior lobe extracts. Later, the pituicytes were considered to be secretory cells. However, considerable evidence exists to support the view advanced by E. Scharrer and B. Scharrer that the active principles are actually elaborated by the cells of the hypothalamic nuclei, stream down the stalk and are stored in the neural lobe.

Regulation of Secretion of Hypophyseal Hormones.—Three mechanisms were implicated in the release of hypophyseal hormones: neural, hormonal and neurohormonal.

Adenohypophysis.—As of the mid-1950s it appeared doubtful that the innervation of the anterior lobe plays a role in regulating the secretion of its hormones. Considerable controversy existed as to whether any fibres from the hypothalamico-hypophyseal tracts enter the anterior lobe. Certainly, if such an innervation exists at all, it is too inconstant and slight to assume any major role in the regulation of the activity of the lobe. Furthermore, the parasympathetic and sympathetic nerves to the adenohypophysis appear to be vasomotor rather than secretomotor in nature.

There was considerable evidence of a neurohormonal control of anterior lobe secretion with some unidentified substance being liberated from the hypothalamus by appropriate stimuli and reaching the anterior lobe cells by way of the hypophyseal portal blood system. It

was also evident that the level of circulating hormones from target endocrine glands has a profound effect on the secretory activity of the pituitary. Thus, injection of thyroid hormone (thyroxin) leads to depression of pituitary thyrotropic hormone while removal of the thyroid or interference with its ability to secrete thyroxin leads to increased secretion of thyrotropin by the pituitary. This action by other hormones on the pituitary may be a direct one on the secretory cells of the pituitary or may be mediated through the hypothalamus and the hypophyseal portal system.

Neurohypophysis.—S. W. Ranson and his associates showed that severance of the hypothalamico-hypophyseal tracts by suitably placed hypothalamic lesions led to degenerative changes in the neurons and to atrophy of the neural lobe with depletion of its hormone content and the development of diabetes insipidus. These findings were interpreted as indicating that the hormones were elaborated in the neural lobe but that their secretion and liberation were controlled by the hypothalamic nuclei. However, the findings were also consistent with the Scharrrers' view that the hormones are actually formed in the neurons of the hypothalamic nuclei and merely stored in the neural lobe.

Release of vasopressin from the neural lobe is apparently regulated by osmotic pressure changes in the blood, decrease in osmotic pressure leading to inhibition of the secretion of the hormone and increase in osmotic pressure leading to increased secretion. Release of oxytocin appears to be in the nature of a reflex initiated by external stimuli such as tactile stimuli of the mammary glands. These stimuli apparently pass by afferent neural pathways to the supraoptic nuclei and result in the liberation of oxytocin.

Biological Assay of Pituitary Hormones.—Chemical assay procedures for pituitary hormones were impractical as of the mid-1950s since not all the active principles were isolated and identified and furthermore, they are usually present in small amounts. Recourse must be had, therefore, to biological assay procedures in which the preparation to be assayed is compared quantitatively to a standard preparation of the hormone in question with regard to some specific biological activity. Thus, growth hormone is frequently assayed by its ability to promote growth in the hypophysectomized rat, thyrotropic hormone by its ability to increase the weight of the thyroid or the uptake of radioactive iodine by the thyroid, and follicle-stimulating hormone by its ability to increase the weight of the ovaries of hypophysectomized rats. Methods for assaying posterior lobe preparations include study of the rise in blood pressure in the anaesthetized cat, dog or rat in the case of vasopressin, and the fall in blood pressure in the fowl or stimulation of the isolated rat uterus in the case of oxytocin. In most instances an international standard was developed by the mid-1950s so that results between workers in various parts of the world could be readily compared.

Therapeutic Uses of Pituitary Preparations.—Anterior lobe hormones, with the exception of the adrenocorticotrophic hormone (ACTH) were not widely used in medicine as of the 1950s. In pituitary insufficiency it is easier and more satisfactory to replace the hormones of the target glands, namely, the thyroid, gonads and adrenal cortex, than to administer the appropriate tropic hormone. Adrenocorticotrophic hormone can be used in the various conditions which respond to cortisone, provided the adrenal gland is responsive. Such conditions include acute rheumatic fever, rheumatoid arthritis and various allergic states such as asthma and drug reactions. Because of the rapidity of its action, corticotropin is particularly useful in the acute illnesses. In treatment of chronic conditions, cortisone and similarly acting preparations are usually preferred since they are less expensive and tend to give rise to fewer undesirable side effects.

The most widespread use of commercial posterior pituitary extracts is during childbirth, either for the stimulation of contractions before birth or for the control of uterine bleeding after birth. Posterior pituitary extracts are also used for the treatment of diabetes insipidus, a disease usually associated with injury to the neurohypophysis and characterized by a greatly increased daily output of urine accompanied by an abnormal thirst. See also ENDOCRINOLOGY; HORMONES.

PIT VIPERS, the snake family Crotalidae, are venomous snakes with the elaborate folding 'fang apparatus' of the vipers, but distinguished by the presence of a sensory 'pit' on the side of the face between the nostril and the eye, on each side of the

head. The pit vipers take their family name from *Crotalus*, the best-known genus of rattlesnakes. Beside the rattlesnakes (which include also the smaller massasaugas and pygmy rattlers, *Sistrurus*), the pit vipers include the moccasin and copperhead genus *Agkistrodon*, which has several species in eastern and central Asia in addition to the familiar American forms, the fer-de-lance group (*Trimeresurus*), found in eastern Asia and the East Indies as well as in tropical America, and the wholly American bushmaster (*Lachesis*). Working from the clue supplied by the experiments of Margarete Ros in 1935, which indicated the labial pits of the African rock python to be sensitive to heat radiation, Noble and Schmidt, in 1937, showed that the pit of the pit vipers is a heat-detecting organ, and presumably an aid in the detection of warm-blooded prey at night. (See articles SNAKES; VIPER; RATTLESNAKE; etc.) (K. P. S.)

PIURA, a coast department of northern Peru, area 15,239 sq.mi.; pop. (1953) 540,237. It includes mountainous areas, Cerros de Amatope, in the north, as well as the Andean Sierra in the east and the large Secura desert in the south. The chief rivers are the Chira, a permanent stream, and the Piura. Crops are grown with the aid of irrigation, as there is rainfall only at intervals of years. Cotton growing is highly important, and Piura is known for its supple long-fibre Pima. The large-bush *dspero* (full-rough) cotton, known as vegetable wool, is also a specialty. There are gins and factories for making cottonseed oil and cake; also a crushing mill for castor beans. Other crops include rice, sugar, tobacco, maize, potatoes, yuca, beans, cacao and fruits, for local consumption. Mountain cattle are fattened in the upper valleys, and goats are raised. Charcoal is made from the algaroba tree.

Piura is the centre of petroleum extraction in Peru. Its exports, with the smaller exports of the adjacent department of Tumbes, were for many years the leading export resource of the country and were still important in the 1950s. The oil fields lie along the north-western coast, a narrow belt about 60 mi. in length. The International Petroleum company (U.S.-Canadian), normally produces about 80% of the national output. Its principal working centre is the port of Talara, virtually the westernmost point in the continent, where it has a large refinery and a modern townsite. Ten miles N. of Talara are the Lobitos fields, owned by a British company, and operating on a substantial scale.

The capital of the department is the city of Piura, pop. (1953 est.) 264,400, on the Piura river, 164 ft. above sea level. It was founded by Francisco Pizarro in 1532, on a slightly different site. It has modern facilities and a superior court. A standard-gauge railway runs from Piura to Paita (q.v.), 58 mi., by way of Sullana, a distributing centre for southern Ecuador. Talara is connected with the oil fields by narrow-gauge railways. Improved highways connect the department with the neighbouring southern and eastern departments.

Catacaos, 6 mi. S. of Piura, became a centre of the Panama hat industry, which uses the leaves of the *toquilla* palm (*Carludovica palmata*). (W. Fr.)

PIUS, the name of 12 popes.

PIUS I, SAINT, pope from about 140 to 154. Both the very ancient Liberian catalogue and the Muratorian canon say that he was the brother of Hermas, author of the *Shepherd*.

PIUS II (Enea Silvio de' Piccolomini, known in literature as Aeneas Silvius), pope from 1458 to 1464, was born on Oct. 18, 1405, at Corsignano (later called Pienza after him) near Siena, It. His family claimed to trace descent from Romulus. The eldest of 18 children, he worked on the farm with his father until a priest enabled him, at the age of 18, to go as a poor student to Siena, where he divided his time between severe humanistic studies and sensual pleasure. He was attracted to Florence by the teaching of Filelfo. He became secretary to Domenico Capranica, bishop of Fermo, and went with him to the council of Basle, where he stayed several years (1432-35), changing masters whenever he could improve his position. He was engaged on various errands, some of them dangerous; they included a long journey to England and Scotland on secret diplomatic business. In 1436 he was back at Basle and, although a layman, obtained a seat in the council and exercised considerable influence. Aeneas took an active part in the council after it was transferred to Florence; and though he still declined to take orders, he was given a position on the conciliar conclave which elected Amadeus of Savoy as pope under the

title of Felix V. In return for his services Felix made Aeneas papal secretary.

A new period of his career opened in 1442, when he was sent by the council to take part in the diet of Frankfurt-on-Main. There he met the German king Frederick III, who made him poet laureate and his private secretary. He ingratiated himself with the chancellor, Kaspar Schlick, at Vienna, one of whose adventures he celebrated in a novel, *De duobus amantibus Eurialo et Lucretia*, in the style of Boccaccio. At this period he also wrote his witty but immoral play, *Chrysis*. In 1446 he took orders as subdeacon and wrote that he meant to reform, "forsaking Venus for Bacchus." Aeneas was useful to Frederick as a diplomatist and managed to give all parties the impression that he was the devoted advocate of each. He took an important part in the diet of Nuremberg (1444) and made his peace with Eugenius in 1445. At the diet of Frankfurt (Sept. 1446) Aeneas modified the hostility of the electors to pope and emperor; and he was present at the conference of Aschaffenburg (1447). The new pope, Nicholas V, made him bishop first of Trieste (1447), then of Siena (1449); and Frederick III made him a prince of the Holy Roman empire. He was made cardinal priest of Sta. Sabina in 1456.

The death of Calixtus III (who succeeded Nicholas V) occurred on Aug. 6, 1458. After a hot fight in the conclave, Aeneas was elected (Aug. 19) and took the title Pius II, with a reminiscence of Virgil's "pius Aeneas." The humanists hailed his election with joy and flocked around to secure a share of the good things, but they were bitterly disappointed, as Pius did not prove himself so liberal and indiscriminating a patron as they had hoped. The fall of Constantinople in 1453 made a deep impression upon Pius, and he never ceased to preach the crusade against the Turk. In June 1459 he opened a congress at Mantua to promote the crusade, but both the French and the Germans were annoyed with him for different reasons, and he received little support, no real session taking place till September. He believed that the decline in the papal influence was due to the usurpation of power by the councils, and he now issued (Jan. 1460) the bull *Execrabilis et in pristinis temporibus inauditus*, in which he condemned as heretical the doctrine that the councils were superior to the popes and proclaimed the anathema against any one who should dare to appeal to one.

While Pius was at Mantua war broke out between the French and Spanish in southern Italy, and a rising of the barons devastated the Campagna. Hurrying back to Rome, Pius succeeded in quelling the disorders. This measure still further alienated the pope from the French, with whom he was at that time negotiating for the abrogation of the Pragmatic Sanction of Bourges. The new king Louis XI sent to Pius saying that he had abolished the Pragmatic Sanction (Nov. 1461), hoping in return to get the kingdom of Naples for his countryman René of Anjou. As Pius continued to support Don Ferrante (Ferdinand I), Louis reasserted the ancient liberties of the Gallican Church. At the same time a serious quarrel with the Germans prevented anything's being done toward a crusade. George of Podebrad, king of Bohemia, was plotting to depose the emperor Frederick III, who was supported by Pius. Diether, archbishop of Mainz, took George's side and replied to Pius' measures by appealing to a general council; whereupon he was declared deposed by the pope (1462). The quarrel with King George, who was accused of supporting the Utraquist heresy, continued with increasing bitterness, but without any decisive result, until the death of Pius. In the meantime the pope did what he could to further the cause of the crusade. The discovery of alum mines at Tolfa gave him an unexpected pecuniary resource; and to stimulate the zeal of Christendom, Pius took the cross on June 18, 1464. He set out for Venice, whence he intended to sail for the east; but he was attacked with a fever and died at Ancona on Aug. 14, 1464.

BIBLIOGRAPHY.—Aeneas Silvius was a voluminous author. His orations and letters were considered models of style. His novel, *De duobus amantibus* (printed at Cologne, c. 1468) went into many editions and was much translated (first Eng. trans., *The Goodlie History of the Ladye Lucretia of Scene in Tuslane*, 1560); see text ed. by J. I. Dévay (Budapest, 1904) and new Eng. trans. by F. Grierson (London, 1928). His *Chrysis* has been ed. by A. Boutemy

(Brussels, 1939) and by I. Sanesi (Florence, 1941). The poems *De miseris curialium* (Cologne, c. 1468) were read throughout Europe. The *Commentarii rerum memorabilium quae temporibus suis contigerunt* (printed in Rome, 1584; Eng. trans., Northampton, Mass., 1947-51), a history of his times told in an interesting and rational manner, constitutes his most valuable work. Part of the *Cosmographia*, on "Asia," was printed at Venice in 1477; the complete text, "Europe" and "Asia," *ibid.*, 1501-03. The *Historica Bohemica* was printed in Rome in 1475.

Pastor, *History of the Popes*, Eng. trans., vol. ii-iii (London, 1891-94); T. Buyken, *Enea Silvio Piccolomini, sein Leben und Werden bis zum Episkopat* (Bonn, 1931); G. Voigt, *Enea Silvio de' Piccolomini als Papst Pius II und sein Zeitalter*, 3 vol. (Berlin, 1856-63); W. S. Boust, *Aeneas Silvius* (London, 1908); C. M. Ady, *Pius II: the Humanist Pope* (London, 1913); C. Lucius, *Pius II und Ludwig XI von Frankreich, 1461-62* (Heidelberg, 1913).

Pius III (Francesco Nanni-Todeschini-Piccolomini), pope from Sept. 22 to Oct. 18, 1503, was born at Siena, It., on May 29, 1439. He was made archbishop of Siena and cardinal deacon of S. Eustachio in 1460 by his uncle Pius II, who permitted him to assume the name and arms of the Piccolomini. He was employed by subsequent popes in several important legations, as by Paul II at the diet of Regensburg (1471) and by Sixtus IV to secure the restoration of the ecclesiastical authority in Umbria. He opposed the policy of Alexander VI and was elected pope, amid the disturbances consequent upon the death of the latter, through the influence of Cardinal della Rovere (who succeeded him as Julius II). Pius was a man of blameless life and would doubtless have accomplished much had he lived.

See E. Piccolomini, "Il Pontificato di Pio III," in *Archivio storico italiano*, 5th series, vol. xxxii (Florence, 1903). (X.)

Pius IV (Giovanni Angelo Medici), pope from 1559 to 1565, was born at Milan, It., on March 31, 1499. After studying law at Pavia and Bologna, he entered the service of Paul III and was eventually made cardinal priest of Sta. Pudenziana by him in 1549. The death of Paul IV and the conclusion of the treaty of Câteau-Cambrésis (1559) provided an opportunity for a reconciliation between France and Spain preparatory to a final settlement of the problems caused by the Reformation. Pius IV was elected after a protracted conclave (Dec. 25, 1559) as the man to accomplish these aims. He had long agreed with those who saw a need for definite reforms, but was at the same time shrewd, tactful and experienced in affairs. He took prompt action in bringing the Caraffa, his predecessor's nephews, to trial, which resulted in their execution in March 1561; and after this he gave Carlo Cardinal Borromeo a free hand in reforming the administration of the curia. But his greatest achievement was the successful conclusion of the Council of Trent. Despite the peace between France and Spain, many obstacles stood in the way of this. The emperor Ferdinand still hoped for the eventual return of the Lutherans to the church and so remained in favour of some doctrinal concessions in their favour; Philip II of Spain on the other hand was opposed to any change and barely in favour of the council's resuming its sessions at all; and the Roman curia was absolutely against doctrinal change, however small, though willing to discuss the reform of abuses (partly in the hope that any changes in this direction, or toward a restoration of ecclesiastical discipline, would result in an increase in its powers). To reconcile these different interests was not easy; moreover, Pius had his own views, being prepared to concede communion in both kinds and perhaps also clerical marriage where conditions were such as those obtaining in parts of Germany, provided that his own prerogatives were maintained or even enhanced (see G. Constant, *Concession à l'Allemagne de la communion sous les deux espèces* . . . , Paris, 1923). A year was spent in overcoming these differences and the outcome was an almost unmitigated triumph for the papacy. Thanks to the pope's own conciliatory attitude, imperial opposition ceased, while no more than a discretionary power given to the papacy to allow communion in both kinds in certain circumstances marred the appearance of unrelenting opposition to the challenge of the new doctrines. The council was dissolved on Dec. 4, 1563, and its decrees and definitions were confirmed by the pope in the

bull *Benedictus Deus* dated Jan. 26, 1564. Most significant was the exclusive power granted to the pope for interpreting and enforcing these decisions, which task, constituting the third and final period of the Counter Reformation, was to occupy the next 25 years. Yet this apparently complete triumph of the papacy is deceptive. Pius did not long outlive the conclusion of the legal enactment of the Counter Reformation, and his desire for a continued endeavour to reconvert the German Protestants died with him. Increasingly, the papacy found itself committed to an unwelcome degree of support for the policies of Philip II; and although, as a result, Protestant heresy was not only checked but made to retreat, in the next century Rome found itself the enemy of France, so that the diplomatic triumphs of that country involved a defeat for Rome. This process was not continuous, and Pius IV cannot be blamed exclusively for the eventual outcome of his policy; but, in taking the narrow view that to secure the best interests of the church it was only necessary to defend and to enlarge the papal power, he clearly miscalculated. The easy triumph at Trent was not repeated. Only Portugal, Poland and Austria accepted the decrees without reservation; in France, on the other hand, they were absolutely rejected. Pius died on Dec. 9, 1565.

PIUS V, SAINT (Antonio, otherwise Michele, Ghislieri), pope from 1566 to 1572, was born on Jan. 17, 1504, in the Milanese. At the age of 14 he became a Dominican monk, taking the name of Michele. He was appointed inquisitor in Como, where his zeal provoked such opposition as to compel his recall (1550). The chief inquisitor, Giovanni Pietro Caraffa, convinced of his value, straightway sent him upon a mission to Lombardy and, in 1551, appointed him commissary general of the Holy Office. When Caraffa became pope, Ghislieri was made bishop of Nepi and Sutri (1556), cardinal (1557) and finally grand inquisitor (1558). In this office he was continued by Pius IV, whom, however, he antagonized by his censoriousness and obstinacy. But after the death of Pius IV the rigorists, led by Cardinal Borromeo, had no difficulty in making him pope (Jan. 7, 1566). Retaining his ascetic mode of life, Pius immediately began the work of reform. Decrees and ordinances were rapidly issued; the papal court became a model of sobriety; prostitutes were driven from the city or confined to a certain quarter; penalties were attached to Sunday desecration, profanity and animal baiting; clerical residence was enforced; conventuals were compelled to live in strict seclusion according to their vows; catechetical instruction was enjoined. A new catechism appeared in 1566, followed by an improved breviary (1568) and an improved missal (1570). The use of indulgences and dispensations was restricted and the penitential system reformed.

Pius was the avowed enemy of nepotism. One nephew, it is true, he made cardinal, but he allowed him no influence; the rest of his relatives he kept at a distance. By the constitution *Ad monet nos* (March 29, 1567) he forbade the reinvestiture of fiefs that should revert to the Holy See and bound the cardinals by oath to observe it. In March 1569 Pius ordered the expulsion of the Jews from the States of the Church. For commercial reasons they were allowed to remain in Rome and Ancona, but only upon humiliating conditions. In Feb. 1571 the Humiliati, a degenerate monastic order of Milan, was suppressed on account of an attempt upon the life of the archbishop, Cardinal Borromeo.

The rules governing the Holy Office were sharpened; old charges, long suspended, were revived; rank offered no protection, but rather exposed its possessor to fiercer attack. None were pursued more relentlessly than the cultured, among whom many of the Protestant doctrines had found acceptance. Princes and states withdrew their protection and courted the favour of the Holy See by surrendering distinguished offenders. Venice delivered Guido Zanetti in 1566; Philip II of Spain, Bartolomé de Carranza in the same year; and Cosimo de' Medici, Pietro Carnesecchi in 1567 (receiving as a reward the title of grand duke of Tuscany in 1569). In March 1571 the special Congregation of the Index, as distinct from the Inquisition, was established, and hundreds of printers took flight to Switzerland and Germany. The regret of Pius was that he had sometimes been too lenient. He spurred

Philip II on in the Netherlands and commanded the utter extermination (*ad internecionem usque*) of the Huguenots; he protested against the tolerance shown by the emperor.

In all this work, Pius confirmed Borromeo's belief that a spiritually minded pope was above all else necessary if the decrees of the Council of Trent were to be put into practical effect. The moral standing of the papacy was raised beyond belief and its effectiveness immensely increased by the obliteration of heresy in Italy; and the morale of the church was much improved by the universal insistence on the Tridentine interpretation of its doctrines. Yet it is open to doubt how much of this improvement was due to Pius' continuous use of the Inquisition. Some at least of the credit belongs to the new generation of higher and lower clergy in the several provinces whose attitude was so different from that of their predecessors.

Moreover, Pius' policy had practical disadvantages. It took too little account of the wishes of secular rulers at a time when their support was essential for the defense of the church against heresy. His attitude toward Elizabeth I of England, whom he declared excommunicate and usurper (Feb. 25, 1570) without possessing the means to give force to his judgment, was especially undiplomatic, antagonizing not only England but Spain, France and the Holy Roman empire as well. Much more successful was his organization of a crusade against the Turks, which resulted in the decisive naval victory of Lepanto (Oct. 7, 1571). Pius died on May 1, 1572, and was canonized by Clement XI in 1712.

PIUS VI (Giannangelo Braschi), pope from 1775 to 1799, was born at Cesena, It., on Dec. 25, 1717. After taking the degree of doctor of laws he went to Ferrara and became the private secretary of Antonio Cardinal Ruffo, in whose bishopric of Ostia and Velletri he held the post of *uditore* until 1753. His skill in the conduct of a mission to the court of Naples won him the esteem of Benedict XIV, who appointed him one of his secretaries and canon of St. Peter's. Raised to the prelature in 1758, he was appointed treasurer of the apostolic chamber by Clement XIII in 1766. On April 26, 1773, he was made cardinal priest of San Onofrio. In the four-month conclave which followed the death of Clement XIV, Spain, France and Portugal at length dropped their objection to Braschi and he was elected to the vacant see on Feb. 15, 1775.

Pius had received the support of the representatives of the three crowns and of the anti-Jesuit party upon a tacit understanding that he would continue the action of Clement, by whose brief *Dominus ac redemptor* (1773) the dissolution of the Society of Jesus had been pronounced. On the other hand the *zelanti*, who believed him secretly inclined toward Jesuitism, expected from him some reparation for the alleged wrongs of the previous reign. In the event, Pius proved unequal to the problems of his age. Not only was the church generally considered to be in urgent need of spiritual and institutional reform, but in addition the papacy was almost completely bereft of either power or influence. The religious orders, the essential medium of its influence in the church, were under attack by the protagonists of the Enlightenment, while its traditional allies, the kings and princes of Catholic Europe, were now indifferent to its interests, being concerned only with the possibilities for using the national churches in their schemes for administrative reform. The emperor Joseph II inaugurated, in the *Toleranzedikt* of Oct. 1781, a policy whereby non-Catholic minorities received a large measure of religious toleration and an opportunity to enter the public service. This was followed in the next year by the dissolution of a number of religious houses, which was designed to provide the money for converting the secular priesthood into salaried officials of the state and for abolishing private patronage. Further detailed reforms were intended to abolish certain practices, such as an excessive number of festivals and a superstitious reverence for mystical phenomena, not considered in keeping with enlightened belief. Pius intervened in 1782 by a personal visit to Vienna, but even this tactful approach secured no concessions whatsoever. Without wishing for a break with Rome, Joseph yet saw no reason to modify his policy

in the slightest. The church in the Habsburg dominions remained wealthy and influential, but subordinated to the state. The papacy was ignored there as it was in France, where the preliminaries to the French Revolution were taking place.

The church was not unpopular in France in 1789. At least a substantial minority of the clergy supported the third estate in its demands for constitutional reform. What undermined the church's position arose for reasons quite unconnected with it. The new revolutionary government, at its wits' end for money, turned to the wealth of the church, which it confiscated as a direct backing for its issues of paper currency. It was intended, under the Civil Constitution of the Clergy (1790), to provide for the support both of the secular and of what was to remain of the regular clergy after they had been given the option of renouncing their vows by paying them salaries out of public funds. Other features of the scheme bore a similar resemblance to the designs of Joseph II. Pius took no immediate action, but negotiations were begun to explore the possibilities of modifying the plan. At length, however, when an oath of fidelity to the new constitution was demanded, he denounced the Civil Constitution together with the Revolution itself (brief of March 10, 1791). The French church was completely split, half accepting, half defying the new regime. Pius was on good terms with the allies against France in 1793 and felt that he could rely on them; but in 1796 he saw his territory invaded by Gen. Napoleon Bonaparte. He sued for peace, which was granted on Feb. 19, 1797, at Tolentino; but in the following December a riot in Rome, in which the French general L. Duphot was killed, led to the occupation of Rome itself (Feb. 15, 1798) and the proclamation of a republic. Pius was taken into captivity and died, still a prisoner, at Valence, on Aug. 29, 1799.

The fortunes of the papacy had reached perhaps their lowest point since the middle ages. It was not the only institution to be overwhelmed by the forces unleashed by the French Revolution; but for at least some of its misfortunes Pius himself must be held responsible. He seemed unable to adopt a policy suited to the exigencies of his time. The revolutionary leaders in France, no less than their predecessors the reforming monarchs, were not primarily anticlerical; but the papacy failed to appreciate that the church could not alone expect to be left untouched by the changes that had been set on foot (in France the patriotism of some churchmen was understandably suspect and the wealth of this church offered an obvious answer to the problem of national bankruptcy). Pius VI succeeded in confusing political reaction and religion to such an extent that it may even be asked whether the identification of liberalism with anticlericalism is not the consequence of, rather than an excuse for, his policy.

PIUS VII (Luigi Barnabà Chiaramonti), pope from 1800 to 1823, was born at Cesena, It., on Aug. 14, 1740. He entered the Benedictine monastery of Sta. Maria at Cesena in 1758, when he took the name Gregorio, and held various teaching appointments in the colleges of his order in Parma and in Rome. He became bishop of Tivoli in 1782 and bishop of Imola and cardinal in 1785. Not surprisingly, a seven-month interregnum followed the death of Pius VI in captivity. The central administration of the church had collapsed, and it was at Venice, under Austrian protection, that the conclave took place which resulted in the election of Cardinal Chiaramonti to the papacy on March 14, 1800.

The situation that confronted the new pope did not call for heroic measures. Europe was making its peace with the future emperor Napoleon at Amiens; it behooved the pope to do likewise. Nor was Pius himself completely antagonistic to the ideas which had evolved during the French Revolution. He was anti-Austrian in his sympathies and had already (1797) publicly expressed the view that between true democracy and the church there need be no conflict. In the circumstances perhaps any agreement was better than none. Pius then responded to Napoleon's advances and finally entrusted the detailed negotiations to his very able secre-

tary of state, Ercole Cardinal Consalvi. The concordat of 1801 solved the problem of the conflicting claims to recognition of the constitutional and of the *émigré* bishops, settled the fate of the confiscated church property and laid down the future relations between church and state. Catholicism was declared to be the religion of the great majority of the French people (so admitting the possibility of official sanction for the exercise of other faiths); the hierarchy was to be salaried by the state (so allowing the old church possessions to remain with their new owners); and the dioceses were completely reorganized (so permitting a fresh start to be made with the appointment of bishops). Thus there was re-established in France a church with at least some of the characteristics and privileges of its pre-Revolutionary predecessor. It was not in fact the articles of the concordat itself which were to prove so distasteful to the papacy but the "organic articles" appended to them by the unilateral action of the French government in 1802. These forbade the exercise of any papal jurisdiction in France except with the permission of the government. Pius protested and tried to use the occasion of his formal consecration of Napoleon as emperor in 1804 to have them modified. He was not successful, and from that time onward relations between him and Napoleon rapidly deteriorated. Rome was occupied by French troops in 1808, and Napoleon declared the papal states to be annexed to France in 1809; Pius excommunicated the invaders and was thereupon taken prisoner. Such he remained until the allies invaded France in 1814. During his imprisonment he was brought to assent to a most humiliating concordat at Fontainebleau on Jan. 25, 1813, but he renounced it two months later, and it disappeared with Napoleon in 1814.

The papacy now faced a brighter prospect. Emerging from captivity, Pius appeared in the role of martyr and was received with tumultuous acclamations on his journey back to Rome in May 1814. At the congress of Vienna, Consalvi secured the restoration of the papal states, while the return of the legitimate monarchs promised a welcome relief from the torment of dealing with revolutionaries. Experience had taught Pius to disavow his earlier liberal leanings, and his policy after 1815 sought to re-establish the church on its old foundations. The territorial changes effected by the congress of Vienna required corresponding changes in diocesan boundaries, and so the opportunity was taken to conclude a series of concordats with the states affected. Consalvi worked to reform the administration, the Jesuits were restored (1814) and recognition was given, after some hesitation, to the new Latin-American republics in revolt against Spain. But at bottom the restored papacy remained in a critical position. It was in no doubt that it should condemn the Revolution and all its works; but the restoration of the *status quo ante*, even where it was possible, had often meant no more than a renewal of the old conflicts which had been all but fatal even before 1789. Thus Francis I of Austria maintained the ecclesiastical institutions erected in the Habsburg lands by Joseph II, while Metternich thought of the pope as just one of a number of Italian princes whose actions required careful watching lest Austrian interests be endangered. Louis XVIII of France affected a support for the church which was shallow, for his actions followed those of his predecessors, jealous of papal interference within their dominions. An attempt to replace the concordat of 1801 with one more favourable to the papacy (1817) was dropped when the French government met with opposition to it in France. From the other flank danger arose out of the discontent felt in Italy against the abolition of the social reforms brought about under Napoleon and, in particular, out of the activities of the Carbonari, a liberal secret society condemned by Pius in 1821.

It was indeed becoming plain that the cure for the ills of the church lay not in concordats of the traditional type with monarchs whose motives were not unmixd and whose own positions were insecure, but in freeing the church from the restraints of the state. To do this it was necessary to bring the national churches closer to the pope and to reassert the absolute supremacy of the pope in spiritual matters. This was the teaching of Joseph de Maistre, and while Pius VII and Consalvi still put their first trust in princes, they gave sufficient encouragement to ultramontanist for it to

become established as a real alternative to Josephism and Gallicism on the one side and to revolution on the other. Perhaps the foremost need of the church at this time was for a breathing space in which it could think out its future salvation. Pius VII provided this by his consistent refusal to resort to extreme or precipitate action. If his policies frequently proved unfruitful, at least it may be said that, when he died, on Aug. 20, 1823, he left the papacy in a better position than he had found it.

Pius VIII (Francesco Saverio Castiglioni), pope from 1829 to 1830, was born at Cingoli, It., on Nov. 20, 1761. He studied canon law at Rome and became vicar-general at Anagni and later at Fano. He was made bishop of Montalto in 1800 and bishop of Cesena and cardinal priest of Sta. Maria in Traspontina in 1816. Appointed grand penitentiary, he was made bishop of Frascati in 1821; and next year he became prefect of the Congregation of the Index. In the conclave following the death of Leo XII, Castiglioni, the candidate of France, was elected pope, on March 31, 1829. He accepted the July revolution in France and was considered to have liberal leanings but was prevented from leaving any impression upon events by his death on Nov. 30, 1830.

Pius IX (Giovanni Maria Mastai-Ferretti) was pope from 1846 to 1878, the longest pontificate in history. He was born on May 13, 1792, at Senigallia, It., the fourth son of Girolamo Mastai-Ferretti, gonfalonier of Senigallia, and the countess Caterina Solazzi. He first came into prominence as archbishop of Spoleto from 1827 to 1832 at a time of revolutionary disturbance. He was made bishop of the important diocese of Imola in 1832, but it was not until 1840 that he received the hat, as cardinal priest of SS. Piero e Marcellino, the delay being generally ascribed to the disquiet caused by his liberal views. He was not, in 1846, the most prominent liberal candidate likely to succeed Gregory XVI; but it took the conclave only two days to determine his election (on June 16, 1846) and so prevent that of the conservative Luigi Lambruschini. He took the name of Pius in deference to the memory of Pius VII, who had been his friend and who had, like him, been bishop of Imola. The choice was in some sense prophetic, for "Pio Nono," as his predecessor had done, began his career sympathetic to liberal ideas only to learn by bitter experience that they too often incorporated the principles of anticlericalism. In 1846, however, all this lay in the future and Europe was agog to view the unusual spectacle of a liberal pope.

The Revolution of 1848.—The new pope was confronted by a difficult situation. All Europe, save perhaps Metternich, considered that the papal states stood in urgent need of reform. A memorandum drawn up in 1831 by the French, Austrian, Russian and Prussian ambassadors in Rome (with the British representative in Florence subscribing) had suggested that councils should be elected to assist in local government, that a central body, composed partly of elected representatives, should control finance and that the dominant position held by the clergy in the administration and in the judicial system should be terminated. Liberal opinion clung to these measures as absolutely essential throughout the pontificate of Gregory XVI. In addition, the papacy was constantly under attack by Italian nationalists as one of the instruments through which Austria maintained its domination over the peninsula. Pius recognized that the papal administration, if not so corrupt and despotic as its opponents asserted, was inefficient and intolerant; and he was sufficiently Italian to resent Austrian interference. Above all he saw the need for the papacy to possess a greater measure of popular support. Yet he was never a revolutionary. He believed that the interests of the church must always come first, and he appreciated that the conservative Catholic powers such as Austria were entitled to consideration for the practical support that they had given the church in the past. That he should eventually disappoint his revolutionary supporters

is not surprising, and Pius himself was early aware of this possibility. A criticism more substantial than that of tergiversation is that he chose to depart from the traditional policies of his predecessors without possessing any definite plans for avoiding the pitfalls that must surround the paths of a pope endeavouring to ally himself with liberalism and nationalism.

Pius wasted no time. He declared a general political amnesty on July 16, 1846, and followed it by a number of practical reforms, including a reorganization of the criminal procedure. Some financial reforms of an administrative character came next, and the censorship was mitigated. Finally came Pius' most daring innovations, the political reforms announced in 1847. The council of ministers became a cabinet of departmental heads of which only the secretary of state was of necessity to be a cleric; it was to be advised by a council of 24 elected members; and a municipal government was established for Rome which included an elected representative body. At the same time, the papacy brought support to the cause of Italian nationalism when Pius ordered the Austrian government to withdraw from Ferrara the reinforcements sent to its garrison there and opened negotiations with Piedmont for a national customs union.

The year of revolutions, 1848, began with revolution in Sicily; soon all Europe was ablaze and Pius was faced with demands, both liberal and nationalist, much beyond what he had been prepared to grant. On March 14 he was compelled to grant a constitution establishing a two-chamber parliament with full legislative and fiscal powers subject only to the pope's personal veto. On March 23 Charles Albert of Sardinia (Piedmont) declared war on Austria. For a time Pius continued to endeavour to steer a middle course, claiming in his allocation to the cardinals of April 29 that he was a disinterested spectator of the revolutionary activities sweeping Italy and that his program of reform was merely the fulfilment of the program long pressed upon the papacy by the powers. In the atmosphere of the time such sentiments were judged as displaying absolute hostility to the national cause, and the papacy was never again able to appear in Italy as anything other than a bulwark of reaction. To prevent revolution from breaking out in Rome itself, Pius consented to the appointment of popular ministries, but neither Terenzio Mamiani nor his successors Edoardo Fabbri and Pellegrino Rossi were able to control the situation. A steadily deteriorating situation culminated in the assassination of Rossi on Nov. 15. A radical ministry was appointed under Emanuele Muzzarelli and Giuseppe Galletti, and when the Swiss guards were disbanded the pope was a virtual prisoner. On Nov. 24–25, with the aid of the French and Bavarian ambassadors, he fled to Gaeta in the kingdom of Naples. In his absence, elections were held for a constituent assembly; and this, on Feb. 9, 1849, declared the temporal power at an end and a democratic republic to be established. The papacy thereupon issued a formal appeal to the rulers of France, Austria, Spain and Naples, but not Piedmont, for assistance. Although it was generally considered that the pope's restoration could take place only with some sort of undertaking to maintain constitutional government in the papal states and although Louis Napoleon, the newly elected president of France, was in favour of such a policy, Pius held out against any concessions and asserted his determination to exercise his temporal power without any restrictions whatsoever. The upshot of a period of military and diplomatic manoeuvre on the part of France and Austria was the unconditional restoration of papal rule by the French general N. C. V. Oudinot on July 15. The revolution was over, and Pius himself returned to his capital on April 12, 1850.

The Roman Question.—It has often been asserted that Pius returned to Rome a changed man, that the former liberal had become a narrow reactionary. That his policy had changed there is no doubt, but his fundamental attitude remained the same. The interests of the church had always been his first concern and he could never be an unconditional ally of nationalism or liberalism. He had been prepared to countenance both while they left the church intact, but experience had taught him that both led to revolution, which he had never been prepared to countenance. Furthermore, political concessions on his part had led to attacks on his

spiritual power, and he considered that it could be protected only by his continued exercise of a temporal authority. Once these two aspects of his dominion had become indissolubly linked, it is easy to see why Pius considered himself obliged to oppose any alteration of his position as a temporal ruler. This is, of course, only to say that the pope can never be a successful temporal sovereign, being unable to make those compromises which statesmanship demands, and that the contradiction inherent in his position does exist. In 1846 Pius had considered that a new departure was necessary to meet the legitimate demands for reform within the papal states and perhaps also those for a change in the Italian system of states; he had experimented and failed and he now considered that he could do no more. But the problems that he had tried to solve remained, and to substitute no policy at all for one that had failed was no answer. The new secretary of state, Giacomo Cardinal Antonelli (*q.v.*), into whose hands diplomacy was now entrusted since Pius recognized his own inadequacies in that field, considered throughout that, in endeavouring to retain the temporal sovereignty untouched, he was fighting a losing battle but had no practical alternative to a policy of inaction. So, not for the first time in history, the papacy was a spectator while events changed the map of Europe.

Most of the administrative reforms carried out immediately after Pius' accession remained, and the papal territories benefited from the general increase in European prosperity after 1850. But constitutional government was never restored; the amnesty granted on the pope's return was so riddled with exceptions as to be worthless; and to all expressions of national sentiment the papacy was utterly hostile. It was not that papal government was tyrannical but that it formed an absolute barrier in the way of Italian unification upon which politically minded Italians were set. So relations with Piedmont, where Count Camillo Cavour became chief minister in 1852, grew steadily worse. What began as a dispute over the terms of a new concordat took on a much more serious aspect when Cavour found it politically expedient to encourage anticlerical feelings during the passage of a law in 1855 dissolving a large number of religious houses. Certain of papal opposition, Cavour began in the same year his plans to achieve Italian unification under the leadership of Sardinia-Piedmont alone. At Plombières in 1858 he agreed with Napoleon III to combine to eliminate Austria from the Italian peninsula and so to settle the fate of Italy between them. Pius declared his neutrality in the war which broke out in April 1859, fearing that the victory of either of his protectors would leave him at its mercy. The Austrian defeat and the armistice of Villafranca resulted in the pope's losing control over the Romagna but nowhere else. Sporadic negotiations for the establishment of an Italian confederacy under the presidency of the pope went on during the winter of 1859-60, but the pope's refusal to contemplate the loss of any part of his dominions brought them to an end. In Jan. 1860 Cavour (who had resigned in protest against the armistice) returned to power, possibly as a direct consequence of the pope's intransigence, and agreed with France to cede Savoy and Nice in return for a free hand everywhere in Italy except at Rome itself. The newly raised papal army was defeated at Castelfidardo on Sept. 18, and the papal states were quickly overrun. French troops protected the Patrimony of St. Peter, which alone of his dominions still remained in the pope's hands.

For ten more years the remnant of the temporal possessions were retained by virtue of the presence of a French garrison at Rome. Cavour himself was favourable toward an agreed settlement of the Roman question on the basis of a continuing papal sovereignty over all the states of the church but with its exercise entrusted to the king of Italy. A start was made to begin negotiations, but then the pope suddenly withdrew. In less than a year, Cavour had died (June 1861), and it was clear that the pope would be able to hold his remaining territories just so long as Napoleon III was willing and able to maintain the French garrison in Rome. When the Franco-German War broke out that was no longer possible. On Sept. 20, 1870, Italian troops occupied the city; and in October a plebiscite was held in which an overwhelming majority of the votes cast were for the incorporation of Rome

in the kingdom of Italy. Pius remained for the rest of his days a prisoner, as he regarded himself, in the Vatican. He refused any intercourse with the Italian government, so that their relations rested upon a law passed by the Italian parliament in November. The sovereignty of the pope was declared to be untouched by the loss of his dominions, in compensation for which he was to receive an annual sum of money. He was to be entitled to conduct his own diplomatic relations with other powers and to have exclusive authority within the Vatican itself and a small district around it. In the rest of Italy, church and state were to be separated. So, though the papacy did not formally recognize the fact till the concordat of 1929, the Roman question had been settled.

Ultramontanism.—Important as the events just described were for the papacy, the doctrinal developments of Pius' pontificate, which spring directly out of these political disasters, constitute its most significant contribution to papal history. Ultramontanism began with Joseph de Maistre, as a reaction against Gallicanism and against Josephism, seeking to free the church from the chains of secular control by binding it more closely with the papacy. H. F. R. de Lamennais developed it by suggesting that the church would benefit from a general increase in political freedom. Gregory XVI condemned Lamennais's teaching because he saw that freedom might mean freedom to deny religion altogether. Pius IX decided in 1846 to experiment with liberalism, but later became convinced that Gregory XVI had rightly suspected it. Nevertheless, if Italy taught Pius one lesson, developments in France, where the church prospered more under the liberal regime of Louis Philippe than it had under the clerical Charles X, suggested quite the opposite conclusions to the liberal Catholics there, whose spokesman was now Charles de Montalembert. On the other hand, the coming of the Second Empire stimulated the party led by Louis Veuillot, whose ultramontanism was of the older sort, completely divorced from liberalism and seeking freedom for the church in an authoritarian state that would guard it against revolution.

For a period after 1850, Pius' policy took little heed of either brand of ultramontanism. Antonelli followed the paths of Consalvi (*see above, Pius VII*) in seeking to procure more favourable concordats with Catholic rulers. Most important was that with Austria (1855), the home of Josephism; and others were concluded with Spain (1851, 1859), with Portugal (1857), with Würtemberg (1857), with Baden (1859), with Nassau (1861) and with a number of Latin-American states (1852-62). Such agreements might be politically valuable but were no defense against intellectual anticlericalism; and Pius became increasingly convinced that the real danger to the church lay in the modern secular ideas which the liberal Catholics were endeavouring to incorporate into its doctrines. The events of 1860 finally convinced him that the notion of a "free church in a free state," as dear to Montalembert as it was to Cavour, was a snare. The encyclical *Jam dudum cernimus* (March 18, 1861) denounced not only Piedmontese aggression but all modern political doctrines, which, it said, encouraged non-Catholic religions, allowed all freedom to attack the church in print and sought always to undermine the authority of the church. The Risorgimento not only convinced Pius that liberalism in the church must be destroyed, but also placed the liberal Catholics in the difficult position of appearing to support those who had caused him so much distress. In every way the ground was being cleared for a new departure. The alternative to Montalembert's doctrine was no longer an unconditional attachment to the principles of the *ancien régime* but a new kind of ultramontanism which asserted the necessity of concentrating authority within the church in the hands of the pope. The ground was being prepared for the Vatican council and for the doctrine of papal infallibility.

But first the strong liberal party in the Catholic church had to be defeated. In 1863 Montalembert was invited to address a large Catholic congress at Malines, and he took the opportunity to defend the concept of a free church in a free state and to condemn intolerance in principle, citing as an example the revocation of the Edict of Nantes. Pius was content in reply to point out that on these two points he was running counter to authoritative

pronouncements of Pius VI and Gregory XVI. This was sufficient to deter Montalembert from accepting a second invitation to Malines in 1864; but his supporter F. A. P. Dupanloup proved an able substitute. Meanwhile at a congress at Munich, in 1863, J. J. I. von Döllinger had pleaded for the right of a scholar to pursue independent inquiry. It was clear to everyone that the church stood in need of authoritative pronouncements about its relations with the state and with modern society, and discussion began about the possibility of calling an ecumenical council for this purpose. But once again the Roman question intervened decisively in the struggle. On Sept. 15, 1864, the French and Italian governments came to an agreement whereby the French garrison was to be withdrawn from Rome within two years. In fact, it was not finally withdrawn until the outbreak of the Franco-German War, but the conclusion of the September convention was sufficient to decide Pius to take immediate action against liberalism now that the final disaster was threatened. On Dec. 8, 1864, he issued the encyclical *Quanta cura* with, attached to it, the famous *Syllabus* listing 80 of the "principal errors of our times." As the errors listed had already been condemned in allocutions, encyclicals and other apostolic letters, the *Syllabus* said nothing new and so could not be contested. Its importance lay in the fact that it published to the world what had previously been preached in the main only to the bishops and that it made general what had been previously specific denunciations concerned with particular events. Thus perhaps the most famous article, the 80th, stigmatizing as an error the view that "the Roman Pontiff can and should reconcile himself to and agree with progress, liberalism, and modern civilisation" sought its authority in the pope's refusal, in *Jam dudum cernimus*, to have any dealings with the new Italian kingdom. On both scores, the *Syllabus* undermined the liberal Catholics' position, for it destroyed their following among intellectuals and placed their program irrevocably out of court. Though Dupanloup tried to explain away the *Syllabus* by insisting upon its context and by stressing its purely negative aspect (thus, though the concept of toleration as the final and universal answer was condemned, it did not follow that intolerance was universally valid), the *Syllabus* nevertheless dealt a mortal blow at liberal Catholicism, which ceased after 1864 to be the main issue taxing Catholic contraversialists. While some of Louis Veuillot's followers hoped that at the forthcoming council a positive statement of the orthodox doctrine of the position of the church in society would replace the negative denunciations of the *Syllabus*, the majority looked upon that battle as won and so turned to the question of defining the pope's infallibility, the keystone of the neoultramontane program of centralizing the authority of the church in Rome so as to escape from the control of the secular state. Conversely, the former liberal Catholics ranged themselves in opposition to this project. When the council at last met, on Dec. 8, 1869, everything was ready for a last decisive engagement.

The Vatican Council.—In the doctrine of papal infallibility itself there was nothing new. It had been employed to define, on Dec. 8, 1854, the dogma of the Immaculate Conception (*q.v.*) which asserted that the freeing of the Virgin Mary from all taint of original sin had occurred at the moment of her conception. The pope had previously made extensive inquiries among the bishops and other divines and there was little opposition to such an exercise of his undoubted prerogative. When, however, at a gathering of bishops and other dignitaries of the church in Rome in 1862 and again at another in 1867 it had been suggested that the doctrine of infallibility should be authoritatively defined, Dupanloup had led a successful opposition to the project. It was objected that such a definition was inopportune, tending to widen the breach between the church and modern society, and that it would present a one-sided view of the source of authority in the church; for while the pope possessed powers issuing directly from God, so too did the bishops, for instance, whose ordinary jurisdiction arose, not out of their nomination or institution (whether by the state or by the church), but equally from divine origin; so that the pope's powers ought not to be defined without reference to other aspects of the nature of the church. The criticism

that must attach to Pius is that he allowed, even encouraged, the council to put aside discussion on the wider issue, which was its original program, in favour of the narrower definition. This was, of course, precisely what the ultramontane party desired. The ultramontanes, indeed, undoubtedly possessed the backing of by far the greater part of the church, partly because of the reaction engendered by the political misfortunes of the last decade, partly because of the immense prestige enjoyed by Pius as a result of his long and tragic pontificate, but to a larger extent because of the contemporary movement away from intellectualism and in favour of devotional religion. Pius himself was at the front of this movement and received strong support from the Jesuits, whose influence was now most emphatically increasing.

The Vatican council (*q.v.*) opened on Dec. 8, 1869, the day of the feast of the Immaculate Conception, which Pius chose for the majority of the important acts of his pontificate. The opposition, consisting of the German, French and U.S. bishops, was strong enough to prevent a definition of the doctrines and nature of the church on the lines suggested by the *Syllabus*; but the ultramontane party, led by Archbishops H. E. Manning (of Westminster) and V. A. Dechamps (of Malines) brought forward the question of infallibility, upon which their position was much stronger. Pius intervened decisively to alter the procedure of the council on Feb. 20, 1870, and on April 29, and to make known his personal support for Manning and Dechamps. The outcome was to postpone all deliberation except that upon infallibility. The decisive vote came on July 13 when 451 voted for it, 88 against it and 62 in favour of some amendment. Thereupon the minority left Rome and the final definition was carried on July 18 by 533 votes to 2. Infallibility (*q.v.*) was confined to those occasions upon which the pope made pronouncements *ex cathedra*; but these pronouncements were to take their authority from God and not from the consent of the church, and no mention was made of any other divine authority existing in the church except that of the pope. There is no doubt that this act secured the triumph of the ultramontane party or that the decisive element in it was provided by Pius himself.

The Prisoner in the Vatican.—Pius reigned for a further eight years during which he became further estranged from the Italian government and witnessed a general outbreak of anticlericalism in western Europe. In Germany this culminated in Bismarck's *Kulturkampf*, which Pius condemned in the encyclical *Quod nunquam* of Feb. 5, 1875, leaving the solution of the problem to his successor. Pius died on Feb. 7, 1878, having seen in his long pontificate the creation of the modern papacy. The exact responsibility of Pius for the events of his pontificate is still a matter for controversy. The result is clearer. Church and state were now finally separated, authority in the church was centralized in Rome and the church was ranged in opposition to the dominant political forces of the day. On the last score alone, Pius was condemned by many of his contemporaries; the 20th century, however, was to see nationalism develop into fascism and revolutionary principles into communism. Whether the separation of church and state reinforced anticlericalism or inoculated the church against its effects is less certain. But perhaps the most damaging criticism of Pius is that he assumed almost the sole direction of events while never appreciating their significance. The great events of his pontificate occurred despite him rather than because of him. Thus he condemned in the *Syllabus* that very separation of church and state which it was the work of the Vatican council, to which for the first time the secular Catholic rulers were not invited, to secure. At one time or another Pius was served by the leaders of all the important movements of his century, by liberal cardinals like Pasquale Gizzi, by ecclesiastical statesmen like Antonelli and by the saintly Manning, a convert from Protestantism. Yet it is unfair to say that he changed his principles; rather he never possessed any, save in his personal religious life, that were not rather naïve, and so he was always open to be guided by experience. In view, however, of the benefit that has accrued to the church from the loss of the temporal power, it should at least be asked whether it was not Pius' determination to maintain it at all costs that contributed most to the temporal power's being lost.

Fliche and V. Martin, form an authoritative guide to all previous literature. See also E. Vercesi, *Pio IX* (Milan, 1930); F. Hayward, *Pie IX et son temps* (Paris, 1948); G. Mollat, *La Question romaine de Pie VI à Pie IX* (Paris, 1932); C. Butler, *The Vatican Council* (London, New York, 1930); G. Weill, *Histoire du catholicisme libéral en France* (Paris, 1909); A. Monti, *Pio IX nel Risorgimento italiano* (Bari, 1928).

PIUS X, SAINT (Giuseppe Melchiorre Sarto), pope from 1903 to 1914, was born of humble parents on June 2, 1835, at Riese in the province of Treviso, It. He studied theology at Padua and was ordained priest in 1858. For 17 years he acted as parish priest at various places in Venetia until his appointment in 1875 as canon of the cathedral and superior of the episcopal seminary at Treviso. He refused the bishopric of Treviso in 1880, but accepted that of Mantua in 1884, at the command of Leo XIII. He was created a cardinal on June 12, 1893, and nominated patriarch of Venice three days later. In Venice his piety, simplicity and readiness to act in harmony with the Italian government made him very popular. Elected in succession to Leo XIII, on Aug. 4, 1903, he took the name Pius in commemoration of Pius IX.

Pius brought the church back from the diplomatic ways of Leo XIII to the paths mapped out by Pius IX's intransigence. Yet it continued to make its presence felt in European politics through the activities of the parish priests and the opportunities afforded to them of influencing opinion in elections. The new pope was the very man to lead this movement, as he came to the papal chair with a long experience as a parish priest and without having held important office in the curia. The real changes introduced by him lay elsewhere. He had little interest in the social reforms supported by Leo XIII, laying his emphasis rather upon the spiritual work of the church in advocating early and frequent communion. He ceased to pursue actively the quarrel with the Italian government, and something like a *modus vivendi* was reached without either side's formally giving way. It is significant that individual Catholics were allowed to enter Italian politics with a view to combating the parties of the left. But Pius made his most important contribution to the history of the church by his attitude to intellectuals. His own scholarship was entirely theological, and he was utterly opposed to the employment of secular disciplines in subjects affecting the faith. When a body of Catholic intellectuals devoted themselves to a scientific study of the Scriptures and of the history of dogmas and reached conclusions which he considered to be at variance with orthodox belief, Pius took action. In the encyclical *Pascendi* (Sept. 1907) he formally condemned 65 propositions of modernism and denounced all tendencies which aimed at the reform of dogma. It has been claimed that by this action Pius cut the church off from modern scholarship. It is fairer to say that he endeavoured rather to compel the church to conduct its own works of scholarship instead of leaving them to institutions outside its control. A striking example of the new moral attitude of the papacy, as well as the termination of its old concern with diplomacy, is to be seen in Pius' denunciation, at the end of his life, of the powers' recourse to war in 1914 and in his refusal to bless the Austrian cause. Though much of his work was later overshadowed by the changes brought about through World War I, there is little doubt that he confirmed the church in the policies which it had at first adopted of necessity during Pius IX's pontificate. Pius X died on Aug. 20, 1914. He was beatified by Pius XII in 1951 and proclaimed a saint on May 29, 1954—the first pope so honoured since Pius V (see above).

See J. Rivière, *Le Modernisme dans l'Église* (Paris, 1930); A. R. Vidler, *The Modernist Movement in the Roman Church* (Cambridge, New York, 1934); M. Pernot, *La Politique de Pie X* (1906–10) (Paris, 1910).

PIUS XI (Achille Ratti), pope from 1922 to 1939, was born on May 31, 1857, at Desio, It., near Milan. He was ordained priest in 1879. His exceptional success in his studies pointed to a career of scholarship, and up to the age of 60 he was concerned almost exclusively in directing a number of great libraries. He became an expert in palaeography and in the problems associated with library classification. Benedict XV recognized his great qualities of mind and selected him for the diplomatic service. In 1918 he was sent

as apostolic visitor to the new republic of Poland, where he was made nuncio next year. Ratti became a cardinal with the title of S. Martino ai Monti in 1921 and was elected pope in succession to Benedict XV on Feb. 6, 1922.

One event stands out in Pius' pontificate: the signing, on Feb. 11, 1929, of the Lateran treaty between the papacy and the Italian government. This was more than a recognition of the *status quo*, as the agreement was specifically declared to constitute a final and irrevocable settlement of the Roman question. The papacy recognized the establishment of the kingdom of Italy and received in return recognition of its full sovereignty over the Vatican City State. Further, the permanent neutrality of the Vatican and of the papacy in the military and diplomatic conflicts of the world was announced. In future, the pope would intervene in such affairs not as the head of a sovereign state but as head of the church, interested only insofar as he might work for the preservation of peace. He would attend international conferences only when invited to do so. These provisions were to prove of great value to the papacy in World War II. The pope received financial compensation for his surrender of any claim to the old papal states; significantly, it was less than that proposed by Cavour in 1861. At the same time as the Lateran treaty, a concordat was concluded regulating the position of the church in Italy itself (see ITALY: Religion). It established the validity of church marriage, which was to precede, for Catholics, the civil ceremony; provided for compulsory religious instruction in school for the children of Catholic parents; and declared Catholicism to be the exclusive religion of the state.

The part played by Pius in these negotiations was considerable and their successful conclusion owed perhaps most to his appreciation both of the real interests of the church and of the political realities of his age. He was similarly successful in reaching an agreement with the Mexican government, which allowed the church to resume religious services in that country. Another agreement was concluded with the new Nazi government in Germany in 1933, but this was short-lived. The papacy claimed that the state was not keeping its promises and began increasingly to denounce pagan aspects of the regime. Holding communism to be the chief enemy of the church, Pius was favourable to the cause of Franco in the Spanish Civil War; but developments in 1938 brought a change of emphasis, and Pius denounced the new anti-Semitism of Mussolini and, with it, all racial theories, so attacking the element common to all branches of fascism (to which Catholic parties had inclined out of their opposition to communism). The fulfilment of this new departure, under Pius' successor, was to bring the political views of the church back to the middle policy advocated by Leo XIII. Pius died on Feb. 10, 1939. (I. F. B.)

PIUS XII (Eugenio Pacelli) was elected pope on March 2, 1939. Born on March 2, 1876, in Rome, of a family with legal traditions and long associations with the papal service, he studied philosophy and theology at the Capranica seminary, at the Gregorian university and at the Pontifical Institute of the Apollinare and was ordained a priest in 1899. In 1901 he was taken into the papal secretariate of state, though he was also employed elsewhere—notably in work on canon law. Attached to the Sacred Congregation for Extraordinary Ecclesiastical Affairs in 1909, he became secretary of that department in 1914.

In 1917 Pacelli was raised to the episcopate as titular archbishop of Sardes and made apostolic nuncio in Munich, at the time when Pope Benedict XV was advancing his proposals for a compromise peace. He stayed in Munich throughout the troubled period of 1918. After the establishment of the Weimar republic he was appointed first papal nuncio to Berlin, but he did not take up residence there till 1925 because of work connected with negotiating the concordat with Bavaria. In Berlin he was *doyen* of the diplomatic corps and was much taken up with drafting a concordat with the German republic; it was approved by the Prussian *Landtag* in 1929. In the same year he was recalled to Rome and created cardinal priest, with the title of SS. Giovanni e Paolo. Appointed papal secretary of state early in 1930, he supervised the implementing of the Lateran treaty and concordat between Italy and the Holy See. Soon after Adolf Hitler's accession to power in

1933 Pacelli drew up a revised concordat with Germany; but by 1935 the Vatican was complaining about German nonfulfilment of its terms and also protesting against pagan elements in the Nazi ideology, such as the doctrine of racism and the persecution of the Jews.

Before he became secretary of state Cardinal Pacelli was already a widely travelled man. He employed the following nine years to increase still more his knowledge of the world, visiting Argentina (1934), France (1935, 1937), the United States (1936) and Hungary (1938). After 1935 he held the post of chamberlain of the church, by which he automatically took charge of the Vatican when an interregnum occurred upon the death of Pius XI on Feb. 10, 1939.

The conclave for the election of the new pope opened on March 1, 1939. Though Pacelli was a popular candidate, no cardinal secretary of state had been elected pope since 1667. He was chosen on the third ballot on March 2 and crowned on March 12.

The pontificate of Pius XII included the most trying period in papal history since the struggle with Napoleon, and the new pope's experience of world affairs stood the Vatican in good stead. Elected when World War II was imminent, his first addresses as pope consisted of appeals for peace. Vatican diplomacy was then in unusual measure in the hands of the pope himself, who was assisted by the cardinal secretary of state, Luigi Maglione. Pius tried to halt Hitler's attack on Poland and used what influence he could to prevent the war from becoming general. Italy's declaration of nonbelligerence gave the Vatican an opportunity for unhampered activity, and the pope availed himself of it. He published his first encyclical, *Summi Pontificatus* (dated Oct. 20), on Oct. 27 after the partition of Poland between Germany and Russia, writing warmly of the Poles and condemning the totalitarian principles obtaining alike in Germany and the U.S.S.R. The basic ideas of his proposals for peace, outlined in this encyclical, were formulated in a five-point program in his Christmas message in 1939 and were emphasized in his speech to the College of Cardinals on Dec. 24, 1944. He stressed the rights of small nations, the protection of minorities, economic co-operation, disarmament and the influence of religion as the only guarantee of "just and lasting" peace. In pursuit of this policy the pope sent warm messages to the sovereigns of Belgium and the Netherlands when their countries were attacked.

The entry of Italy into the war on June 10, 1940, restricted Vatican communications with the rest of the world, but the pope as sovereign of a neutral state was able to carry on relief work on an extensive scale, notably through the Vatican organization for information about the missing and prisoners. He held aloof from the Nazi-Soviet conflict and established "normal" diplomatic relations with Tokyo. A new period of tension began with the Allied landings in Sicily and the bombing of Rome. During the Nazi reign of terror in the city after the overthrow of Mussolini, substantial numbers of escaped prisoners of war, Jews and leaders of democratic parties were sheltered by the ecclesiastical power.

On the death of Cardinal Maglione in 1944, the pope once more took charge of the secretariate of state; his closest assistants were Domenico Tardini, secretary of the Congregation for Extraordinary Ecclesiastical Affairs, and Giovanni Battista Montini, in charge of the Department of Ordinary Affairs. After the war the Vatican found itself in a position of great, if indirect, power in Italy. The strength of the church was reaffirmed in the general elections of 1948 in which the civic committees of Catholic Action assisted the Christian Democratic majority party in retaining power in the country. Repeated defeats, however, were inflicted on the church in eastern Europe and in the far east, where Soviet Communism was in the ascendant. In Feb. 1949 all concerned in the bringing of the Hungarian primate Joseph Cardinal Mindszenty to trial were excommunicated, and the pope compared "the long chain of persecution" in "certain dictatorial countries" with the persecution of the church under Nero. In July the Holy See formally excommunicated all members of the Communist party and all those who aided or abetted it, pointing out that Communism was materialist and anti-Christian; that it was not permissible for Catholics to publish, distribute or read books, periodicals, papers

or pamphlets which preached the doctrine of Communism, or to write in them; and that those who consciously and freely did so incurred excommunication.

The year 1950 was a jubilee year, and pilgrims flocked to Rome from all parts of the free world. The pope used the occasion to make a number of significant pronouncements. In the encyclical *Summi Maeroris*, he deplored the evils of the new "murderous and inhuman weapons" of war but reiterated his severe strictures on the Soviet system and also castigated those who "insidiously" labelled the Catholic Church with "the accusation of wanting a new conflagration"; another encyclical, *Humani Generis*, condemned certain "false opinions" which threatened the foundations of the Catholic faith, denouncing "lovers of novelty," those who neglected traditional channels of doctrine, evolutionists, existentialists and people who "tried to reconcile opposing opinions in the field of dogma itself"; and on Nov. 1, Pius solemnly pronounced the dogma of the Corporal Assumption of the Virgin Mary.

In 1951 at the traditional New Year's reception for the diplomatic corps, the pope spoke of the horror of war and the desire of "an equitable, freely stipulated peace, immune from all unjust conditions and from all the intolerable burdens" imposed on the peoples of the world. In an encyclical letter, *Evangelii Praecones*, the pope praised missionary progress of the preceding 25 years. He reported that Catholics in mission lands had nearly doubled, the number of Catholic missions had increased from 400 to 600 and the number of native and foreign priests from 14,800 to more than 26,800.

Addressing the international Catholic Congress on Rural Problems, Pope Pius said it must be recognized that industrial capitalism had stimulated agricultural production and had raised the physical and spiritual level of the country people in many parts of the world. Therefore, criticism should not be directed against the capitalist system as such, but against the dangers that would arise if its influence were to alter the specific character of rural life and make the country a mere extension or annex of the city.

Pope Pius XII announced that he opposed any system of socialized medicine that conflicted with the moral principles of respect for man and family. With appropriate safeguards against certain medical practices, however, he held that socialized medicine does not conflict with the principles of the Roman Catholic Church, which welcomes any state initiative in the field.

During 1951 the pope commemorated the 15th centenary of the council of Chalcedon in the encyclical, *Sempiternus Rex*. As a means of imploring divine intervention for peace, the pope, in the encyclical *Ingruentium Malorum*, urged all Catholics to recite the rosary. In a letter to the archbishops, bishops, clergymen and laity of Czechoslovakia, Pope Pius denounced the Communist regime of that nation for its religious persecution and accused the Prague government of carrying on a campaign based on falsehoods. He also issued a decree of excommunication against all Catholics who supported the Czech government's efforts to bring about schism.

On July 7, 1952, Pius addressed an apostolic letter to the people of Russia (*Ad universos Russiae populos*), which was unusual in being addressed not only to Catholics but to a whole nation. It reviewed the history of the church in Russia over the previous 1,000 years and recalled instances when the church had extended both spiritual and material aid to the Russian peoples in time of famine, particularly after World War I.

On Oct. 3, 1953, the occasion of the 6th International Congress on Penal Law, the pope urged adoption by all civilized nations of a code of international criminal law to punish war criminals, including those responsible for starting unjust wars and for mass deportation of populations.

On March 19, 1953, Pope Pius, addressing about 4,000 teachers and pupils of the schools for adult education in Italy, pointed out the urgent need of "awakening an appreciation of political and economic realities in conformity with the Christian concept of life." Adult education should help to preserve the balance between the "constructive activity of individuals in the service of social well-being on the one hand, and on the other the necessary duty of . . . protection and defense of the social order."

Referring to the methods employed by psychiatry, while addressing the fifth International Congress of Psychotherapy and Clinical Psychology, the pope alluded again to what on a previous occasion he had called the "pan-sexual methods of a certain school" and counselled not "to entrust the determining role to one particular factor" and never to advise "conscious action which does not tend towards divine perfection."

The circumstances under which in France and in Italy a large share of the loyalty of the working class was given to the Communist parties led to a marked increase in the attention given to the problems of pastoral care under modern conditions. The experiment of the "worker-priests" in France was found, however, to require some modification by the end of 1953; but the pope's continuing solicitude was exemplified when, in 1955, the Holy Week liturgy was reformed to put an increased emphasis on the role of the laity. In his encyclical *Fulgens Corona* Pius XII proclaimed 1954 as a Marian year; it was marked by special ceremonies in commemoration of the definition proclaimed 100 years before of the dogma of the Immaculate Conception. On Oct. 14, 1953, he dedicated the new Pontifical North American college.

In 1954, though severely ill most of the year, the pope composed a special prayer at the occasion of the Marian year, in which he invoked the protection of the Virgin Mary for the Catholic Church and asked that all men, in her name, recognize that they are brothers. On June 5 the pope issued an encyclical commemorating the 12th centenary of the martyrdom of the English Benedictine missionary St. Boniface, the "apostle of Germany."

Pope Pius XII's Christmas message, on Jan. 3, 1955, called on all nations to live in peace and harmony. On April 3, seemingly fully recovered from his illness of the previous year, the pope made his first Palm Sunday appearance in two years and took part in the ceremonies opening Holy Week. The theme of his Easter message was the hopes and terrors of the nuclear age. Alluding to the U.S.S. "Nautilus," the world's first atomic-powered submarine, the pope said: "Without fear or trepidation we have noted the recent advances . . . of nuclear energy . . . in the service of men."

On Sept. 7, 1955, the pope addressed 1,500 delegates to the tenth International Congress of Historical Sciences. "The Catholic Church," he stated, "does not identify itself with any culture. . . . She is, nevertheless, disposed to maintain relations with all cultures. She recognizes and allows to subsist all that in them is not opposed to nature. But in each one she introduces the truth and the grace of Jesus Christ and thereby confers a deep likeness on them all." Later that year, the pope presided at the seating of the newly appointed scholars in the Pontifical Academy of Sciences.

Pope Pius XII, described as slight and ascetic in appearance and suave and gentle in manner, became noted for his frequent audiences given to pilgrims of all nations, some of whom he addressed in their own languages—French, German and English.

He died on Oct. 9, 1958.

(B. Wl.; X.)

PIZARRO, FRANCISCO (c. 1471 or 1475–1541), discoverer and conqueror of Peru, was born at Trujillo in Estremadura, Spain, about 1471 (or 1475). He was an illegitimate son of Gonzalo Pizarro. Of Pizarro's early years hardly anything is known, but he appears to have been poorly cared for and his education was neglected. Shortly after the news of the discovery of the new world had reached Spain he was in Seville, and from there found his way across the Atlantic. There he is heard of in 1510 as having taken part in an expedition from Hispaniola to Urabá under Alonso de Ojeda, by whom he was entrusted with the charge of the unfortunate settlement at San Sebastian. He accompanied Balboa (whom he afterward helped to bring to the block) in the discovery of the Pacific.

In 1522 he entered into a partnership with a priest named Hernando de Luque and a soldier named Diego de Almagro for purposes of exploration and conquest toward the south. Explorations were then undertaken down the west coast of South America, in which Pizarro was left for months with but 13 followers on the island of Gallo, without ship or stores. There it was that Pizarro displayed the courage which has made famous the story of himself and his companions. (Some authorities, among them Xeres, Pizarro's secretary, give the number of his companions as

16. Herrera states the names of 13; Garcilaso supplies the remaining 3.) But Pizarro persisted until he had coasted as far as about 9° S. and obtained distinct accounts of the Peruvian empire. The governor of Panamá showing little disposition to encourage the adventurers, Pizarro resolved to apply to the sovereign in person for help, and with this object sailed from Panamá for Spain, accompanied by Pedro de Candia, in the spring of 1528, reaching Seville in early summer. Charles V was won over. Pizarro was decorated with the order of Santiago, was granted a coat of arms and 13 of his heroic companions were ennobled by name.

On July 26, 1529, was executed at Toledo the famous *capitulación* by which Pizarro was upon certain conditions made governor and captain general of the province of New Castile for the distance of 200 leagues along the newly discovered coast, and invested with all the authority and prerogatives of a viceroy, his associates being left in wholly secondary positions. One of the conditions of the grant was that within six months Pizarro should raise a sufficiently equipped force of men, of whom 100 might be drawn from the colonies; as he could not make up his due complement he sailed clandestinely from San Lucar in Jan. 1530. He was afterward joined by his brother Hernando with the remaining vessels, and when the expedition left Panamá in January of the following year it numbered 3 ships, 180 men and 27 horses. The subsequent movements of Pizarro belong to the history of Peru (*q.v.*). After the final effort of the Incas to recover Cuzco from 1536 to 1537 had been defeated by Diego de Almagro, a dispute occurred between him and Pizarro respecting the limits of their jurisdiction. This led to battle; Almagro was defeated (1538) and executed; but his supporters conspired, and assassinated Pizarro on June 6, 1541.

Prescott, *History of the Conquest of Peru* (1847); A. Helps, *Life of Pizarro* (1869); Justin Winsor, *Narrative and Critical History of America*, vol. ii (1886).

PIZARRO, GONZALO (1505–1548), explorer, half-brother of Francisco Pizarro, was born at Trujillo in 1505 or 1506. He accompanied the Peruvian expedition in 1531, and received for his services extensive grants in the Potosí mines. In 1539 he was made governor of Quito, and in 1541–42 he led an expedition east of Quito in the course of which Francisco de Orellan explored the Amazon. Two years later he defeated Vela, the new viceroy, and was declared governor of Peru, but in 1548 he was defeated by a Spanish force under Pedro de la Casco, was compelled to surrender and was executed on April 10, 1548.

PIZZICATO, a musical term indicating that a given passage for a stringed instrument is to be plucked by the fingers instead of played by the bow.

PLACE, FRANCIS (1771–1854), radical reformer, was born on Nov. 3, 1771, and later apprenticed to a leather-breeches maker. He suffered great hardships as a result of the decline of this trade, and in 1793 organized an unsuccessful strike of London breeches makers. He acted as secretary to other trade clubs and from 1794 to 1797 was prominent in the London Corresponding society. He used his frequent enforced leisure for self-education, especially in political economy, and became a great admirer of Jeremy Bentham. In 1799 he and a partner opened a tailoring shop in Charing Cross road, and the next year he went into business alone, rapidly becoming successful. He was already known as a Radical politician when in 1814 he took up a campaign to secure the repeal of the Combination acts forbidding trade unions. In 1824, acting through Joseph Hume, M.P., he secured a parliamentary committee which reported in favour of the abolition of the acts. Bills to this effect were carried, amid general indifference; the premier afterward assured the house of commons that he had no idea of the contents of the bills when he recommended them. The immediate effect of the repeal was a sudden increase in the number and activity of trade unions, and the next year the government attempted to restore the prohibition. The public excitement and the interest of the workingmen were such that, after a parliamentary struggle of unusual stiffness, Place secured the passing of an act which scarcely altered the position.

at least temporarily, in all marsupials and most placental mammals. The primitive yolk sac of viviparous Selachii commonly forms a placental relationship with the wall of the uterus. In viviparous fishes gestation usually takes place within the ovary and so the vitelline (and often pericardial) net of venous capillaries becomes intimately associated with the ovarian tissue instead of the uterus. In addition to these more common types of placentation many bizarre and unique structural adaptations for this purpose have been described in a few species among the "lower" vertebrates and even in some invertebrates.

The evolutionary history of the foetal membranes in general and of placentation in particular has been of great interest to biologists for many years. It is a highly complex problem because the structures themselves are very variable and complex anatomically and physiologically; because fundamentally identical types of placentation occur in widely unrelated groups, *i.e.*, in certain lizards, marsupials and placental mammals; and because the type of placentation in one order of mammals may run almost the whole range from a very primitive condition to a highly complex one. Obviously then there are evolutionary series from simple to complex types in several animal groups and these are often rather closely paralleled by similar series in widely unrelated forms. The only tenable conclusion in view of these facts must be that placentation has arisen independently several times in different groups, but that once these adaptations to viviparity have been initiated they have frequently run parallel courses because of parallel physiological conditions to be met and similar structural units or building blocks (chorion, amnion, etc.) to be worked with, inherited from the oviparous ancestors of each.

One extremely interesting and valuable feature of the foetal membranes from the evolutionist's point of view is the fact that they are relatively "conservative" features. That is, they change less rapidly than other portions of the anatomy of the group. For instance, sea lions, dogs and cats belong to the order Carnivora, yet are very different anatomically. But, except for size differences and a few microscopic details, the foetal membranes of all three are almost identical. The same can be said of the Artiodactyla, including the cattle, sheep, goats, deer, etc., and of the Primates where only an expert can distinguish between the placenta and membranes of the great apes and man. This

DR. HARLAND W. MOSSMAN

FIG. 2.—IDEALIZED SAGITTAL SECTION OF THE HUMAN UTERUS IN THE FOURTH MONTH OF PREGNANCY

Comparing this with fig. 1, it will be noted that the villi have disappeared from all but the basal side of the chorion, thus giving rise to a disc-shaped placenta; the decidua capsularis has also disappeared, bringing the smooth chorion into contact with the uterine cavity and opposite wall (decidua parietalis). There also has been considerable fusion of the amnion with the chorion, and the umbilical cord has increased greatly in length.

conservatism makes it possible to see indications of phylogenetic relationships of species and groups where such extreme anatomical modifications have occurred that it has been difficult on other anatomical grounds to determine with what groups they are affiliated. One such group is the order Edentata, where so much adaptive modification of skeletal features, especially of skull and teeth, has occurred that it is impossible to compare their skulls or dentition profitably with other groups. Although knowledge of the foetal membranes of this heterogeneous group is fragmentary, enough is known to show that the membranes of the old world scaly anteater or pangolin (family Manidae) closely resemble those of the more primitive hoofed animals such as the pigs (order Artiodactyla); that the new world anteaters and the sloths (Myrmecophagidae and Bradypodidae) have membranes

which are much alike and that the sloths show many affinities to the Primates; and that the new world armadillos (Dasypodidae) have many features in the development of their foetal membranes which are very similar to those of the Rodentia. It seems probable therefore that

FIG. 3.—SCHEMATIC DIAGRAM SHOWING HOW THE PLACENTA FUNCTIONS BY ALLOWING THE PASSAGE OF NUTRIENTS, OXYGEN, CARBON DIOXIDE AND WASTES THROUGH THE EXTREMELY THIN PLACENTAL MEMBRANE SEPARATING THE FOETAL BLOOD IN THE CAPILLARIES OF THE VILLI (C) FROM THE MATERNAL BLOOD IN THE INTERVILLIOUS SINUSES (S).

these three divisions of the catch-all order Edentata are widely unrelated to one another and that each may be rather closely related to a different order of less highly specialized forms.

BIBLIOGRAPHY.—For further details on the human placenta and foetal membranes see any standard textbook of human embryology, obstetrics or gynaecology. For even more detailed information on the foetal membranes of man and those of other animals, consult: G. W. Corner, C. G. Hartman, C. H. Heuser, W. H. Lewis, A. H. Schultz, G. L. Streeter and G. B. PLACERS, the common name given to the alluvial deposits in which gold frequently occurs. They consist of sand and gravel deposited by existing or former streams of water carrying detritus of gold-bearing rocks. Other metals, *e.g.*, tin, are similarly deposited. The gold of the placers consists of grains called gold dust and larger pieces, rounded by attrition, called nuggets. The placer of an ancient stream may be deep-lying because covered since its formation with other deposits or even lava. (See GOLD: MINING AND METALLURGY.)

PLAFOND, a card game played in France and to some extent in England. Plafond was played in Paris as early as 1918 and was one of the forerunners of contract bridge (*q.v.*). The procedure is almost exactly the same as in contract bridge except for the scoring. Trick values are as in auction bridge: no trump 10, spades 9, hearts 8, diamonds 7, clubs 6; and 30 points in trick points bid and made are required for game. Tricks made but not bid are entered in the honour score at 50 each. There are bonuses of 100 points for a small slam and 200 for a grand slam whether or not these contracts were bid. Undertrick penalties are 100 for each trick (200 if doubled, 400 if redoubled), and the vulnerable feature of contract bridge is not used. Four trump honours in one hand count 100, or 150 if partner holds the fifth; five trump honours, or four aces at no trump, count 200. There is an additional bonus of 50 for making any contract, plus 100 for making a game, plus 400 for winning a rubber.

See A. E. Manning Foster, *Bridge-Plafond* (London, 1933).

PLAGIARISM, an appropriation or copying from the work of another, in literature or art, and the passing off of the same as original. The Lat. *plagiarius* meant a kidnapper, stealer or abductor of a slave or child, though it is also used in the modern sense by Martial (I, 53, 9). (See COPYRIGHT.)

PLAGIOCLASE, an important group of rock-forming minerals constituting an isomorphous series between albite feldspar and anorthite feldspar. (See FELSPAR.)

PLAGUE, in medicine, a term formerly applied to any widespread disease causing a great mortality, but now confined to a specific infectious fever caused by *Pasteurella pestis* (also called *Bacillus pestis* and *Yersinia pestis*).

History of Outbreaks.—Many experts believe that, because of the characteristics of the disease in man and the extent of the mortality in mice, it was true plague that afflicted the Philistines in 320 B.C. (I Sam., v and vi). Another early historical notice of plague is contained in a fragment of the writings of the physician Rufus of Ephesus, who lived in the time of Trajan, preserved in the *Collections of Oribasius*. Rufus described the buboes called pestilential as specially fatal and found chiefly in Libya, Egypt and Syria. This passage shows the antiquity of plague in northern Africa, which for centuries was considered its home. Not until the 6th century A.D. was Europe afflicted by bubonic plague, as part of the great cycle that lasted 50 years. It spread over the whole Roman world, beginning in maritime towns and radiating inland. In another direction it extended from Egypt along the north coast of Africa. Whether the numerous pestilences recorded in the 7th century were caused by *P. pestis* cannot now be said, but the ones in England chronicled by Bede in the years 664, 672, 679 and 683 may have been this disease, especially since *pestis inguinalis* was again recorded in Rome in 690. Several infectious diseases were called plague or pest, so retrospective diagnosis must depend on clinical accounts, particularly of the buboes, the course and the contagiousness.

In the great cycle of the 14th century, when this disease was known as the Black Death, some plague infections were bubonic and some were pneumonic. The number of deaths was enormous, reaching in various parts of Europe two-thirds or three-fourths of the population in the first pestilence, and in England even more. Other countries were much less severely affected. J. F. K. Hecker calculated that one-fourth of the population of Europe, or 25,000,000 persons, died in the epidemic.

Though it had been generally accepted that the second plague pandemic of the 14th century originated in central Asia and spread to Europe, to India and to China, there was no documentary basis for this assumption until the 20th century. The Russian archaeologist D. A. Chwolson discovered two old Nestorian graveyards near the Issyk-kul lake, an area long thought to form part of the central Asia plague focus. Inscriptions on three headstones made in 1338 and 1339 stated that the persons interred had died of plague. Chwolson also noted that the number of graves dating back to these years was exceptionally high. This, considered with other known characteristics of those outbreaks, is good evidence that plague existed in central Asia before it ravaged Europe, India and China.

The great plague of London in 1664-65 was not an isolated phenomenon. Plague had recurred frequently throughout Europe in the 15th, 16th and 17th centuries, but London had been unusually free of it in the preceding years. It was not mentioned in the bills of mortality till in the autumn of 1664 (Nov. 2). A few isolated cases were observed in Westminster, and a few in the following winter, which was severe. About May 1665 the disease again became noticeable and spread, but somewhat slowly. The total number of deaths from plague in that year, according to the bills of mortality, was 68,596 in a population estimated at 460,000. This number is probably an underestimate, since it is likely that many of the 6,432 deaths attributed to spotted fever were really caused by plague. In December the mortality fell suddenly and continued down through the winter, but in 1666 nearly 2,000 deaths were recorded. From London the disease spread widely over the country, but from 1667 on there was no epidemic of plague in any part of England, though sporadic cases appeared in bills of mortality up to 1679. This disappearance of plague from London has been attributed to the Great Fire, but it also subsided in other cities without such cause. The decline has also been ascribed to quarantine, but effective quarantine was actually not established till 1720, so that the cessation of plague in England must be regarded as spontaneous.

Epidemics subsided soon after in most of western Europe. In 1666 plague raged in Cologne and on the Rhine and continued

there till 1670. In the Netherlands there were instances of plague from 1667-69, but no definite notices of it after 1672. France saw the last of plague in 1668, till it reappeared in 1720. In the years between 1675 and 1684 a new epidemic appeared in north Africa, Turkey, Poland, Hungary, Austria and Germany, progressing generally northward. Malta lost 11,000 persons in 1675. The plague of Vienna in 1679 caused 76,000 or probably even more deaths. Prague in 1681 lost 83,000 of its population. Dresden was affected in 1680, Magdeburg and Halle in 1682—in the latter town with a mortality of 4,397 out of a population of about 10,000. Many north German cities suffered about that time, but in 1683 plague disappeared from Germany till 1707. In Spain it ceased about 1681; in Italy certain cities were attacked till the end of the century, but not later.

It is remarkable that in such a short time plague should totally disappear. Various explanations have been offered: the progress of civilization, in particular the control of infectious diseases by sanitation, hospitalization and cleanliness, and the supervision of the infectious sick were considered important factors. The agrarian revolution brought about a change in domestic housing that led to the exclusion of rats from human dwellings, so that the opportunity for infection was reduced. Another factor may be that, with the abandonment of the old trade routes, commercial activity centred in Amsterdam and London, and the new connections with the far east were by sea, not by land. This reduced the distribution of the disease. These explanations are not fully satisfactory, but they doubtless cover auxiliary factors. Knowledge acquired in the 20th century leads to the conclusion that the decline at the end of the 17th century illustrates the great natural law of the rise and decline of epidemics. The seeming disappearance again in the middle of the 19th century was merely a phase of the natural history of the disease itself, no more remarkable than the similar prolonged quiescence that followed the epidemics of the 8th century.

During the 18th and the early part of the 19th century, plague continued to prevail in Turkey, the near east, Syria, Egypt and Greece. The cases in Egypt from 1833 to 1845 play a part in the history of the disease, since they were almost the first to be studied scientifically in their home by skilled physicians, chiefly French. Because this outbreak was less severe than the previous ones, the observers were misled to believe that the disease is not particularly contagious.

An outbreak in 1878-79 on the banks of the Volga near Vetlianka spread another panic across Europe, and most European governments sent special commissions to study and help control the epidemic. Although the foreign commissioners arrived when the epidemic was over, they learned something of the characteristics of the disease. Subsequent research in southern Russia established the region around the Volga as an old focus of campestrial plague.

Once it was a maxim that plague never appears east of the Indus, but during the 19th century it afflicted more than one district of India. In 1815 Gujarat, Kathiawar and Cutch suffered epidemics after three years of severe famine. Again early the next year it struck these same localities and then extended to Sind as far as Hyderabad, and southeast as far as Ahmedabad and Dholera. But it disappeared from these parts in 1820 or early in 1821 and was not heard of again till July 1836, when it broke out with violence at the town of Pali in Rajputana. It spread from Pali to Ajmer-Merwara but died out spontaneously in the hot season of 1837.

In 1823 an epidemic broke out at Kedarnath in Garhwal, a sub-district of Kumaun, southwest of the Himalayas on a high situation. In 1834 and 1836 there were others, and these at last attracted the attention of the government. In 1849 and 1850 and again in 1852 the disease raged and spread southward. In another outbreak in 1876-77 the symptoms of the disease, called *mahamurie* or *mahamari* by the natives, were precisely those of oriental plague, and concurrent deaths of rats were noted.

The third great expansive pandemic is generally thought to have gained momentum in Yunnan province in China, where the rebellion of the Mohammedans beginning in 1855 and possibly the movements of refugees propagated the disease. Progressing in slow stages, it reached the provincial capital of Yunnanfu (modern

Kunming) in 1866, and not until 28 years later did it extend to Canton and Hong Kong (May 1894). The number of deaths in Canton has been estimated at 80,000 to 100,000. During the epidemic in Hong Kong the organism that causes plague, *Pasteurella pestis*, was identified by Alexandre Yersin on June 20, 1894. Ports in south China became plague distribution centres, and between 1894 and 1922 it spread throughout the whole world, more widely than during any great foregoing epidemics. Among the many points infected were Bombay in 1896, Calcutta in 1898, Japan and the Philippines in 1897, Australasia, Hawaii, Central and South America in 1899, Cape Town and San Francisco in 1900, Egypt and Singapore in 1901, Bangkok in 1904, Guayaquil, Ecuador, in 1908, Java in 1910, New Orleans, La., and Colombo, Ceylon, in 1914, Galveston and Beaumont, Texas and Pensacola, Fla., in 1922. Being at that time a seafaring disease it struck nearly all European ports, causing local epidemics in Glasgow, Oporto, Odessa, Naples and Marseilles. India suffered most. The reported number of deaths between 1896 and 1917 was 9,841,396; the maximum, reached in 1907, was 1,315,892—a rate of 5.16 per thousand of the population. Fortunately in the ensuing 25 years the incidence curve turned downward toward greatly diminished prevalence. In 1923 there were not more than 250,000 deaths, by 1942 only 10,577; the figure rose to 41,745 in 1947, dropped to 9,757 in 1948 and went down to 1,007 deaths in 1952.

The usual statements that nothing definite was known about the transmission of plague during the early outbreaks is not entirely correct. Himalayan villagers long ago believed that unusual death among rats preceded outbreaks among human beings, and centuries earlier in the Israel-Philistine controversies mice were suspected of being in some way concerned. Avicenna mentions plague in animals, and, according to Nicephorus Gregoras, mice died in 1348 during the Black Death in Constantinople. There can be no doubt that by that time a highly efficient plague reservoir, the black rat *Rattus rattus*, had become firmly established in Europe. The significance of rat mortality was again brought up in the Pali outbreak in India in 1837. From the time of the Canton epidemic, it had been noticed that plague in rats had concurred with plague in man. The relationship was so striking that in 1897 Ogata described the Formosa outbreak as "ratpest." Paul Louis Simond noted the frequency of the disease among those who had recently handled rats and the major role of the rat in its spread. It was reserved for the Plague Research commission to discover, in Bombay in 1905-06, the exact link between rats and human disease. As the result of studies of the Indian outbreak made by the Advisory committee, appointed in 1905 by the secretary of state for India, the Royal society and the Lister institute, the whole epidemiology of plague was elucidated.

Geographic Distribution and Prevalence.—The distribution of plague in man depends almost solely on its distribution and course in rodents. Once this was recognized, measures were taken to stop the transportation of rats and their fleas, and these measures were remarkably successful in confining plague to areas where it prevails in domestic and wild rodents. Transportation of infected rodents and fleas, once responsible for the spread across broad geographic areas, through well-planned and well-executed efforts, was almost eliminated. From 1920 to 1951 the only proved instance was on board the S.S. "Ville de Tamatave" in April 1938 at Beirut. Rat-proofing, fumigation of cargoes and general control measures in ports have freed the world of ship-borne plague. A change in the disease itself—away from the ports of warm countries toward the cooler hinterlands—also contributed.

Asia.—The principal active plague centres in Asia by the middle of the 20th century were in India, China and Burma. There are three endemic centres near the foot of the Himalayas, one in central India comprising the watersheds of the Vindhya, Baner and Maikal ranges and the Mahadeo hills, and three centres in the watersheds of the Western Ghats in Bombay and Mysore, in Hyderabad state, and in the districts of Salem, Nilgiris and Madura. These foci have been very active. Plague there early in the 1950s was both a rural and an urban problem—it moved from the commercial towns out to villages and flared up where it found a highly susceptible rat population. The epizootics on the warm,

tablelands were severe, the mortality among rats was high, and the disease ebbed in a short time. In the cooler regions, like the watersheds, the disease was enzootic, persistent and less fatal to rats.

In China, outbreaks varying in intensity were perennial in Hong Kong until 1923. Canton was free from the end of World War I till 1954, but the infection remained entrenched east of Pakhoi where 627 cases were recorded from Jan. to Sept. 1950. From Kwangtung it spread to other coastal provinces, of which Fukien continued to be involved. Another series of outbreaks, also preponderantly bubonic, was dispersed along inland routes from Mongolia. Plague also reappeared in Yunnan province about 1938. North Manchuria, infected by human agency from the wild rodent foci in outer Mongolia, suffered pneumonic plague epidemics in 1910-11 (more than 60,000 deaths) and a smaller outbreak (10,000 deaths) in 1920-21. Because these did not include the local rat population, they ended as soon as the climate ceased to favour spread of the infection from man to man.

Plague continued in Burma (only 646 deaths in 1950 compared with 2,743 in 1946), Indochina and Thailand (not more than 100 cases a year) and Java (about 2,266 deaths in 1951; 829 in 1952). In Saigon in 1943, an epizootic among domestic mice, more heavily infested with the commonest plague-carrying fleas than were rats, was responsible for 42 cases of bubonic plague. The infection among wild rodents in the interior of western Asia was in part responsible for plague invasions of Syria and Israel (a few cases in Jaffa and Haifa in 1946 and 1947), but the scarcity and sporadicity of the cases in Israel from 1941-47 led to the suspicion that the infection there may have been taken in by sea.

Europe and Africa.—After World War II, plague appeared in Europe only in Ajaccio on Corsica, in Taranto, It., and on Malta and the Azores. Information about its real prevalence in the steppes of the southern U.S.S.R. is not available.

North and northwest Africa recorded infection in Egypt (712 cases in 1943-44), Tunisia, Algeria, Morocco and French West Africa (639 cases in Dakar in 1944). Central Africa—in particular Uganda, Kenya, Tanganyika and the Belgian Congo—had campestrial foci of long standing, but the incidence of cases was usually less than 400 a year. On Madagascar the outbreaks in ports and along the coast were bubonic, but on the high plateaus the infection tended markedly to secondary lung involvement and on to pneumonic plague, which accounted for 56.2% of all cases seen there in 1946.

Plague gained a foothold in the Union of South Africa in 1900, when the Boer War necessitated the importation of large amounts of forage from infected South American ports. Until 1912 port areas were involved, but thereafter infected rodents and fleas spread plague to rodents in southwestern Transvaal and northwestern Orange Free State, in the Cape Midland and near Port Elizabeth where cases began to occur after 1919. Human infections numbered 556 from 1919 to 1925, 466 from 1925 to 1931, 687 from 1931 to 1937 and 646 from 1937 to 1949.

North America.—In the United States plague was first recognized in San Francisco in 1900. Up to 1904, when San Francisco was declared plague free, 121 persons had been infected and 113 of them died. Evidence that rats were the source of this outbreak is abundant. The disease broke out again between May 1907 and Nov. 1908, when there were 159 cases and 77 deaths. Plague-ridden rats, as many as 2% of those trapped and examined, were caught in badly infected districts of the city. In New Orleans, 30 persons became infected in 1914, 25 (11 deaths) in 1920. At the same time Florida and Texas were reporting human plague (total of 41 cases). Between 1924 and 1955 there were no outbreaks of human plague of murine or urban origin.

As the result of a case of plague in a human being in 1903 the squirrel was added to the list of reservoirs. A few human infections were later traced to contact with squirrels or bites by their ectoparasites: a small epidemic of pneumonic plague (13 cases) in Oakland, Calif., in 1919 and a similar one in Los Angeles in 1924 (31 cases). A human infection was recorded in the Great Basin area in Oregon in 1934. Although the infection is endemic among a large number of rodents throughout rural areas of western states, it rarely spreads to man.

Hawaii.—Plague became manifest in Honolulu in Nov. 1899 and spread to adjacent districts and to Kauai, Maui and some other islands of the archipelago. Between 1899 and 1949, the total of human cases reported was 416. The Hamakua district (Hawaii) has suffered several human infections.

South America.—Plague has been endemic in South America at least since early in the 20th century—in Venezuela, Brazil, Peru, Bolivia, Argentina and Ecuador. Flea-borne bubonic plague has been the commoner form, but in mountainous areas the proportion of pneumonic infections is much higher.

Venezuela reported, from 1910 to 1951, 211 cases, 37 of them in Miranda and Aragua. Brazil was more afflicted—between 1899 and 1949, at least 9,248 persons were infected. In Argentina about 7,000 infections were recorded between 1899 and 1940. Bolivia was infected in 1928. Rat epizootics preceded some outbreaks there. Peru has had more bubonic plague than any other American country (22,254 cases until 1952); it has not been free of plague since 1903. The infection among wild rodents was established in Guayaquil in Ecuador as early as 1908 and spread from there to Chimborazo and Loja provinces, causing more than 2,700 human infections between 1909 and 1940, after which a limited number of cases have been recorded each year in the mountainous areas.

Causative Organism.—The plague bacillus, identified in 1894 by Alexandre Yersin, is found in the local vesicle of the flea bite, in buboes in ordinary cases, in large numbers in the blood in so-called septicæmic cases and in the sputum in pneumonic cases. Post mortem it is found in great abundance in the lymph nodes, spleen, bone marrow and liver. Outside the body the plague bacillus is not very resistant to heat or to chemicals, but it remains viable in dried sputum for at least three months and in dry flea faeces held at room temperature for five weeks. It is resistant to cold; cultures and organs held in the icebox retain their virulence for months, even up to ten years. On the whole, the capacity of the bacillus to multiply in the tissues and to cause death of its host—the virulence of the organism—is remarkably stable and vigorous. Test animals, for example mice, have been fatally infected with as few as three to ten bacilli. Most investigators agree that the virulence of the organisms does not subside in the course of a bubonic outbreak. The mildness of some infections may be explained by greater resistance of certain individuals, not by inherent differences in the causative micro-organism. Strains of *P. pestis* secured from man, rats, wild rodents and fleas from every corner of the world are biologically identical and show remarkable homogeneity of virulence and infectiousness. With special laboratory methods certain strains may be rendered avirulent or they may spontaneously lose their virulence when kept in the laboratory. Unfortunately most of these avirulent strains are somewhat toxic. They are, however, suitable for active immunization and also are used in the manufacture of antiplague serums.

Natural History.—Plague is primarily a disease of rodents, and man enters only accidentally into the usual cycle. This cycle—rodent-flea-rodent—as a rule is enzootic, but under certain environmental conditions it reaches epizootic proportions. It includes wild rodents in wooded areas (giving it the name "sylvatic plague"), in desert and rural areas (giving it the name "campestral plague"), in uninhabited or only sparsely settled by man and, unfortunately for human beings, in commensal rodents, mainly rats and mice. Human beings only rarely contract the disease from the wild rodents; in the midst of epizootics that have littered pastures with cadavers of plague-infected squirrels, when burrow openings were teeming with infective fleas, rarely if ever has a human being been infected. But spread of the infection among domestic rodents in the vicinity of human habitations creates conditions favourable for outbreaks of human plague. For when an epizootic reduces the rodent population, fleas from the dead animals fail to find another rodent host and thus begin to infest man. At first the cases are sporadic, but under suitable conditions large numbers of persons may be included.

As a rule, at this stage if the infection is bubonic, plague does not spread directly from one person to another. Relatively rarely are there enough bacilli in human beings to infect the fleas that ingest their blood. The human flea, *Pulex irritans*, is a poor trans-

mitter of plague. Under certain circumstances when the bacilli become localized in the lung and are eliminated in large numbers in respiratory discharges, and when environmental and climatic conditions favour aerogenic droplet transmission, the infection spreads from man to man. The pulmonary plagues in Manchuria in 1910-11 and 1920-21 and later in eastern India amply attest to the importance of cool weather and crowding in badly ventilated dwellings as contributory factors in creating pneumonic epidemics. The term "epidemic" is used loosely to describe bubonic plague, for this relatively seldom spreads from man to man.

Infection may also be acquired at post-mortem examinations and in the course of laboratory accidents and was once used with homicidal intent (in Calcutta in 1933, described by Wu Lien-teh and his colleagues in 1936).

Rodents carrying plague fall into two main groups: (1) the Muridae, the rats, of which certain species living in close association with man are responsible for maintaining endemicity and for large outbreaks, and (2) the Sciuridae, Cricetidae, Jaculidae, Caviidae and Leporidae, the wild rodents, responsible for maintaining campestral and sylvatic plague.

Murine or Rat Plague.—Natural plague has been observed in a great variety of the order Rodentia, but of numerous species of Muridae only three Murinae are of universal importance in plague. The rats largely responsible for propagating plague are the Norway or brown rat (*Rattus norvegicus*) and the English black rat (*Rattus rattus rattus*), with its subspecies or varieties. In different areas different subspecies of *Rattus* and several species of *Mus* may be responsible reservoirs. The organism is ordinarily discovered through macroscopic and microscopic examination of the organs of the diseased or dead rats routinely collected in plague-infected communities.

Plague in Wild Rodents (Campestral and Sylvatic Plague).—Among the wild rodents, squirrels and related species are the chief instruments for exchange of the infective agent; a group of small rodents such as harvest mice and multimammate mice act as complementary and auxiliary hosts. There is ample evidence that plague has spread from wild rodents to domestic rats and mice. More than 100 species are subject to natural infection, not infrequently taking the form of a seasonal epizootic among the younger members of the regional wild rodent population.

The Vector.—Members of the family Pulicidae are the third indispensable factor in the propagation of plague. Simond, in his experiments with fleas, in 1898 showed them to be possible disseminators of bubonic plague, either from animal to animal, animal to man, or man to man. The ecology of wild rodent fleas has been well studied to the conclusion that comparatively few of the estimated 1,500 existing species can transmit plague. The most important vectors are listed in the accompanying table. The classical one is the Indian rat flea, *Xenopsylla cheopis*.

At one feeding on a rat whose blood contains 100,000,000 organisms per millilitre, a flea will ingest about 5,000 organisms and

Vectors of Plague

Flea (known to bite man)	Distribution	Reservoir hosts	Transmits primarily to:
<i>Xenopsylla cheopis</i>	Widely disseminated	<i>Rattus rattus</i>	Rats and man
<i>Xenopsylla brasiliensis</i>	Uganda, Kenya, Nigeria	Rats	Rats and man
<i>Xenopsylla hawaiiensis</i>	Island of Hawaii	Field rats	Field rats
<i>Xenopsylla astia</i>	India, Ceylon, Burma, Mesopotamia, Mombasa	Rats	Rats
<i>Xenopsylla nubicus</i>	Tropical east and west Africa	Rats	Rats
<i>Xenopsylla philoxera</i>	South Africa	Wild rodents	Wild rodents
<i>Pulex irritans</i>	Nearly cosmopolitan	Man, swine, rodents, carnivores	Man, rodents
<i>Nosopsyllus fasciatus</i>	Temperate zone of Europe and America	<i>Rattus norvegicus</i>	Rats
<i>Dipodomys montanus</i>	Western United States	Ground squirrels	Ground squirrels
<i>Polygenis platensis cisandinus</i>	South America	Cavies	Cavies, or cuys, and man
<i>Delostichus talis</i>	Southeast U.S.S.R.	<i>Cricetus</i>	<i>Cricetus</i>

<i>Oropsylla silantiewi</i>	Manchuria	Rodents (tarabagans)	Rodents

will ordinarily become infective because the organisms are likely to multiply in its digestive tract. The flea is not a mere passive carrier. A few days, or even longer, after it has fed on infected blood, under the microscope clusters of plague bacilli can be seen in its stomach. Later its proventriculus becomes plugged by gelatinous masses of bacilli, and the valvular action becomes inadequate. Because of this obstruction, the blood being sucked by the flea cannot enter its stomach. The oesophagus containing virulent bacilli becomes distended, and the elastic recoil of the walls of both pharynx and gullet when the flea stops sucking may drive back into the bite wound highly infective blood. The infective flea may regurgitate as many as 11,000 to 24,000 organisms at one biting. Some of these usually enter the blood of the new host, and if the new host is susceptible, bubonic or septicæmic plague is the result.

Many species of fleas merely become infected, but blockage does not occur; they rarely if ever become pestiferous. Others may carry the bacilli in their intestinal tubes for a long time and become blocked later. This last relationship between the flea and the plague bacillus is quite important because in it may lie one explanation for the carry-over of the infection from season to season in hibernating rodents.

Fleas that have fed on severely infected rodents may spread the organisms with their mouth parts without being blocked. This mode of transmission is of particular importance during epizootics when plague is rampant. There is experimental evidence that this type of mechanical transmission by a large number of fleas is as efficient in spreading infection as is the bite of a single blocked flea.

Of least importance is faecal transmission. The flea pellets are viscous and unless the skin is broken, plague bacilli could not gain entrance into the tissues of the bitten. Furthermore, not all faecal pellets contain enough organisms to overcome the inherent high resistance of many wild rodents.

Killing of vermin (lice or fleas) with the teeth may cause tonsillar infection with the plague bacillus.

The maximum life span of an infective flea with a blocked proventriculus is only 20 to 30 days, but infected unblocked fleas may live much longer. A flea infected in October can retain the infection and transmit it during the following March. Among the preservers of plague from season to season, the flea is probably important. The microclimate of subterranean burrows with a constant moderately high temperature and a constantly low saturation deficiency is particularly favourable to the longevity of the flea.

Transportation of infected fleas in all kinds of cargo is frequently assured when the time of transport is not too long and climatic conditions are favourable.

The type of fleas and the extent of flea infestation of rats in an area have been stressed as factors in the severity of an outbreak. The total number of fleas per rat varies with the climate, the season and other factors. But, on the basis of epidemiologic comparisons, these factors are of less importance than the number of infected fleas that become blocked and therefore infective.

Detecting campestral or sylvatic plague among wild rodents in rural areas is greatly facilitated by the examination of their fleas, removed either from fur or burrow openings.

Clinical Characteristics of the Human Disease.—Plague may take three clinical forms: bubonic, pneumonic or septicæmic. Misleading use of the word "bubonic" has given rise to the erroneous idea that true plague is necessarily bubonic and that non-bubonic types are a different disease altogether.

The illness varies within the widest limits, exhibiting all gradations of severity from mere indisposition, which may pass almost unnoticed, to extreme violence, equalled only by fulminating cholera. The mild infections are always bubonic; the other forms are invariably severe, almost always fatal unless treated. The incubation period is usually three to six days; it may be as short as 36 hours or as long as ten days. As a rule the onset is sudden and well marked.

Bubonic plague constitutes about three-fourths of the total cases. In a typical case there is usually shivering at first, occasionally a rigour—followed by a rise of temperature, with vomiting, headache, giddiness, intolerance to light; pain in the epigas-

trium, back and limbs; sleeplessness, apathy or delirium. The headache is described by the patient as splitting; delirium is usually of the busy type, like delirium tremens. The temperature varies greatly; it is as a rule not high on the first day—from 101° to 103°—and may even be normal, but sometimes it rises rapidly to 104° or 105°, even to 107° F.; it frequently falls two or three degrees on the second or third day. The eyes are red and inflamed. The tongue, somewhat swollen, is at first covered with a thin, white fur, except at the tip and edges, but later it becomes dry, and the fur yellow or brownish. Prostration is marked. Constipation is the rule at first; the occurrence of diarrhoea is a grave sign. Frequently the severely ill patient appears dazed and stupid, is thick of speech and staggers, giving the impression of drunkenness. There is nothing, however, in all these symptoms and signs that is positively distinctive of plague. The really pathognomonic sign is the appearance of buboes, or inflamed nodes, which happens early in the illness, usually on the second day; sometimes they are present from the onset, sometimes they cannot be detected before the third day or even later. The commonest seat is the groin, and next to that the axilla; the cervical, submaxillary and femoral glands less frequently affected. Sometimes the buboes are numerous and on both sides of the body, but more commonly on only one side. The pain is described as lancinating. If the buboes are not treated, they usually suppurate and open outward by sloughing of the skin, but they may subside spontaneously or remain hard. Petechiae appear over buboes or on the abdomen shortly before death. Boils and carbuncles are rare.

Pneumonic plague was described in many of the old epidemics; its precise significance was first recognized by L. F. Childe in Bombay, India. He found the bacilli in the sputum and showed that the inflammation in the lungs may be set up by primary plague infection. The pneumonia is usually lobular, the onset marked by shivering, with difficult and hurried breathing, cough and expectoration. The prostration is great and the course of the illness rapid. The breathing becomes very hurried—40 to 60 respirations in a minute—and the face dusky. The expectoration soon shows an admixture of blood, and later in the disease usually large amounts of blood-containing sputum teeming with plague bacilli are coughed up. The temperature is high and irregular. The physical signs are those of bronchopneumonia; oedema of the lungs soon supervenes, and death occurs in three or four days.

When the organisms are injected by the flea directly into the capillaries or cannot be localized in the buboes, generalized septicæmic plague may develop. Prostration and cerebral symptoms are particularly marked. The temperature rises rapidly and very high. The patient may become comatose and die within 24 hours but more commonly on the second or third day. Recovery is rare.

Recovery from all three forms is slow. Second attacks are rare.

Diagnosis.—In an endemic area, typical severe bubonic or pneumonic plague is relatively easy to identify. However, when the disease breaks out only sporadically, the bubonic form must be distinguished in its early stages from tularaemia, lymphogranuloma venereum and pyogenic infections. In the tropics the septic and pneumonic forms may resemble various fevers—relapsing, dengue, typhus or fulminating malaria. Primary pneumonic plague has been confused with influenza, as in the Oakland, Calif., outbreak, or with lobar pneumonia, as in the Los Angeles outbreak. There may be no clinical signs from which diagnosis can be made; bacteriologic examinations are essential. These include microscopic examination of oedema fluid from a bubo or of sputum, serum haemagglutination, agglutination and complement fixation tests.

Early diagnosis is of greatest necessity, not only to the patient, whose recovery may depend on immediate treatment, but also to his family and physician and to the community because of the infectivity of this disease agent.

Treatment.—A highly potent horse antiserum prepared at the Haffkine institute in India was proving quite effective in the treatment of plague shortly before the remarkable successes were achieved in 1940 with sulfonamide therapy. Experimental and field trials assessed and confirmed the value of antibiotic treatment of all forms of plague, provided the drug is given early in

the course. Supplementing drug therapy with inoculation of anti-serum apparently offers the severely infected a better chance for recovery. Some of the antibiotics—streptomycin, chloramphenicol and the tetracycline compounds terramycin and aureomycin—are excellent in the treatment, even of pneumonic plague; the sulfonamide compounds, though less curative, are highly useful and offer highly relevant advantages.

In countries where the antimicrobial drugs are scarce and expensive and where plague still causes many acute illnesses and deaths every year, the inexpensive sulfa drugs have a sound position in both the cure and the prevention of this infection. In field trials the antibiotics set a new record in lowering the mortality rate in pneumonic plague in which the prognosis was formerly so poor. In general the consistently satisfactory experimental and field trials with streptomycin, marred only a little by the development of streptomycin-resistant strains of the plague bacillus, make it the first choice among the available antiplague drugs. Chloramphenicol, terramycin and aureomycin are active against the streptomycin-resistant strains.

Prevention.—The suppression of bubonic plague is attempted by (1) appropriate sanitary measures directed simultaneously against the vectors and the rodent reservoir, (2) efforts to enhance the resistance of the individual and (3) isolation of the sick and the handling of all infectious material with the greatest caution.

Since plague-infective fleas represent the immediate hazard to man, it is imperative that insecticides be used early in the outbreaks. Rat ectoparasite control with the insecticide DDT (dichloro-diphenyl-trichloroethane), introduced and tested during World War II, achieved spectacular and consistent control of *Xenopsylla cheopis* and other fleas that carry and transmit plague. Dusting rat runs with DDT brings epidemics under control. This is the method of choice to speed up a suppressive program and to increase its effectiveness. Not only does it kill the ectoparasite on the rats, but some of the powder is carried by the rats back to their nests and harbourages, and this is distributed over the breeding places of the fleas. Under certain circumstances the chemical kills even the rats. During an epidemic, houses are effectively disinfected with DDT-aromex soap, which remains effective for weeks if not longer.

Because fleas acquire their infections by feeding on plague-infected rats, it is equally important that these reservoir hosts be effectively controlled in order to eliminate the source of the disease agent. For destroying large numbers of rodents, poisoning and fumigation are more effective than trapping. Red squill, phosphorus, barium carbonate, arsenic trioxide, zinc phosphide and thallium sulphate are some of the poisons commonly used before World War II. Research during the war produced ANTU (alpha-naphthyl thiourea) and 1080, the latter with an unprecedented oral toxicity for rats. The lethal anticoagulant Warfarin, developed in 1948, consistently reduces rat populations of *Rattus norvegicus*, *R. rattus* and *Mus musculus*, but not *R. hawaiiensis*. It has the advantage that it is self-baiting and can be given in cornmeal. Proper use of all rodenticides requires considerable skill and experience. Since some of the preparations (1080, ANTU and others) are highly poisonous for mammals, including man and domestic animals, adequate safety precautions must be employed.

No rat control program is complete without supportive sanitation and until harbourages are destroyed and buildings are rat-proofed. Importation of rats from endemic areas should be guarded against by rat-proofing ships, applying measures to prevent the escape of rats from vessels and their entrance of ships from the wharves. This is accomplished by rat guards on the hawesers. Rat-proofing and the use of rodenticides have reduced the necessity for fumigation of ships.

Suppressing wild rodent plague in rural districts is almost impossible. The area is usually of unmanageable size, and knowledge of the many ecologic factors that influence control operations is so inadequate that, except in a few small areas in California, and, according to the Russians, in the Caucasian steppes, curtailment of the rodent population cannot yet liquidate plague among the species involved. For this reason it is essential that domestic premises be surrounded by rodent-free belts.

In an outbreak, persons engaged in rat control should be immunized and should wear flea-proof clothing. While flea repellents do not prevent fleas from alighting, the insects do leave impregnated surfaces without biting.

Vaccination or the injection of antigens made from killed virulent organisms are used to immunize inhabitants of epidemic regions. These do not invariably prevent infection, but they do reduce the morbidity and mortality rate of bubonic plague. The steady decrease of plague in Indonesia was attributed to the use of vaccines consisting of living avirulent plague organisms. Equally favourable results were reported from Madagascar with this type of preparation. Workers in India, using the so-called Haffkine, heat-killed broth culture of a highly virulent strain, showed repeatedly that the total number of cases and the death rates are lower in the vaccinated than in the unvaccinated groups. Whatever means is used, repetition of vaccination strengthens the immunity produced.

Unless the necessary precautions are taken, pneumonic plague spreads from one person to another, and some additional measures must be taken against the other forms. Strict isolation of the patients in insect-proof rooms is essential. The patient's clothing must be disinfected and disinfested of fleas in a steam sterilizer. All those who come in contact with patients must wear gloves and gowns. If the infection is pneumonic or suspected of being pneumonic, physicians, nurses and any others in contact with the patient must be protected by complete overalls, gloves, hoods equipped with goggles and face masks of eight layers of gauze covered by a deflection mask. The air of the room in which patients with pneumonic plague are housed, preferably under an oxygen tent, should be kept dry; possibly other auxiliary protective measures against aerogenic infection deserve consideration. The chance of infection through droplets or droplet nuclei is quite high and infection of medical personnel not infrequent. Persons other than medical attendants who are exposed to plague pneumonia must be quarantined for seven days, and chemoprophylaxis with sulfadiazine may be instituted.

PLAICE (*Pleuronectes platessa*), a flatfish that ranges from Iceland and northern Europe to south of Great Britain, and one of the most important commercial fishes of the North sea. Other species of somewhat similar form, with large eyes on the right side and with a small terminal mouth, are the dab and flounder; from these the plaice is easily distinguished by the red spots scattered over the body. The pharyngeal bones are strong and bear large blunt teeth, used for crushing the shells of the bivalves that are the principal food of this species. A length of more than 30 in. and a weight of 8 lb. may be attained, but nearly all the fish marketed are less than half that length.

PLAINFIELD, a city of Union county, New Jersey, U.S., 24 mi. W. by S. of New York city; served by the Baltimore and Ohio, the Central of New Jersey and the Reading railways. Pop. (1950) 42,366; and 37,469 in 1940 by federal census. With the adjacent boroughs of North Plainfield and South Plainfield the population of "the Plainfields" was 62,984. At an altitude of 105 ft. near the Watchung hills, Plainfield is a residential suburb of New York. There are five golf courses in and near the city. A number of manufacturing plants had an aggregate output in 1950 valued at \$25,000,000. The city's assessed valuation for 1950 was \$66,926,654 and the total tax rate \$5.34 for each \$100 valuation. Settlement there dates from 1684 by colonists from Scotland. Around a gristmill built on Green brook in 1760 and a Quaker meetinghouse (still standing) removed from its ancient site

(1713) to its present location in 1788, there was formed a village named Milltown. Upon the opening of a U.S. post office in 1800 the name was officially changed to Plainfield which became an incorporated city in 1869. The free public school system in the state of New Jersey was started there in 1847.

PLAINS INDIANS. The tribes of the central portion of the North American continent, on the open plains and parkland prairies extending from Alberta and Saskatchewan to Texas and from the Rocky Mountains almost to the Mississippi river, formed a natural unit, both in environment and culture. Essentially, this territory is the habitat of the American bison (buffalo); and on this animal the Plains tribes primarily depended for food, shelter, clothing and many utensils, and to its habits many of their customs were adapted. The eastern tribes, in the prairies, seasonally combined bison hunting and maize farming; the western ones, in the plains proper, were wholly nomadic. Originally, they transported their tents and belongings on travois frames dragged by dogs. After the introduction of the horse by the Spaniards, beginning about 1650, this animal gradually replaced the dog, tribal movements became freer, while their numbers augmented and their culture elaborated. They camped in large circles of tipis, conical tents of bison skins supported by long poles leaning on a primary tripod (or four poles)—a highly specialized, convenient dwelling quickly pitched and struck. Cooking was by roasting, or with hot stones in bison rawhide containers; meat predominated heavily in the diet. Property and food were stored and transported in rawhide bags and "parfeches." Clothing was of deer (antelope, elk) skins, supplemented by bison robes, and was well tailored, ample, comfortable, and often highly ornamented with embroidery of porcupine quills, later beads. Social organization was simple: matrilinear clans, patrilinear clans, or non-exogamic bands, according to tribe. Warfare was constant, being carried on partly for profit (horse raiding) but chiefly for honour, a man's career depending directly on the prestige of his war exploits; hence arose the system of "counting coups," that is, publicly recounting blows struck on enemies. The best known ritual was the so-called Sun dance. Most other rites were conducted by societies, which among some tribes were age-graded. Supernatural power was sought in visions by most men, warriors as well as curers. There were sacred "bundles" for tribes, clans and societies; these were fetiches preserved for generations.

The Plains tribes are proud, brave, out-spoken and direct, and possess an unusual sense of individuality and personality. The physique is exceptionally tall, rangy and hardy. With their long braided hair, fringed costume, eagle feather war-bonnets, mounted on ponies, with tipis as a background, the Plains tribes have captured the imagination of recent generations of whites; and pass popularly as the most representative of Indians. The most typical Plains tribes are the Dakota, Assiniboine, Blackfeet, Gros Ventre, Arapaho, Cheyenne, Kiowa, Comanche; others are the Sarsi, Plains Cree, Plains Ojibwa, Wind River Shoshone, Mandan, Hidatsa, Arikara, Pawnee, Omaha, Ponca, Iowa, Oto, Missouri, Kansas, Osage, Wichita, Kiowa Apache; and, among the tribes in or across the Rocky mountains, the Kootenay, Flathead, Nez Percé, Bannock, Ute and Jicarilla Apache have been especially influenced by Plains culture. The preponderant stock is the Siouan; next, the Algonkin; Shoshonean, Athabascan, Caddoan are also each represented by two or more tribes.

See C. Wissler, "Indians of the Plains" (*Am. Mus. Nat. Hist.*, 1912) for a general summary; and monographs or books by G. Catlin, W. P. Clark, E. H. Curtis, G. A. Dorsey, J. O. Dorsey, A. C. (A. L. K.)

PLAINSONG or PLAIN CHANT. A general term for a certain style of unisonal music, comprising chiefly the church-music called "Gregorian" which belongs to Rome, and that called "Ambrosian" which hails from Milan. But the other Western collections of church-music, much less well-known than these, and a good many groups of Eastern church-music could also quite properly be put under this heading.

Origin.—There are various factors in the genesis of music which determine its essential characteristics. Music intended for a

dance is necessarily regular in its rhythm; so also, though less tied, is music which is set to metrical verse. On the other hand music fitted to a prose text is not so regular. Thus there arise different kinds of rhythm in music, ranging from strict time to the freest of movement. Again some music arises from recitation and the need to declaim some words artistically and audibly; while other music aims at melody, that is to say a succession of sounds, which is pleasant for its own sake, and would be so independently of any words.

The ecclesiastical music which is called plainsong is so named because it is unmeasured music, not regular in rhythm, a *cantus planus* as contrasted with *cantus mensurabilis* or measured music. It is this feature that chiefly differentiates it from modern music; and at the same time allies it with such things as sea-chanties, counting-out rhymes, and the like. The Christian church, like other worshipping bodies, requires euphonious sounds for the recitation of its psalms, and for the reading of its scriptures in public. As these passages are not (for the most part) written in any strict metre, the music to be provided is essentially a "plain" chant; there are several classes of such plainsong.

Influence of the Psalter.—The chief influence in this evolution has been that of the Psalter. Hebrew poetry follows a metrical system, but this disappears in translation. There survives however, a more obvious feature of the original, viz., its parallelism. This consequently becomes a prominent characteristic of certain sorts of plainsong, so that the chants directly derived from the psalms take a binary form. The recitation demands a reciting note, on which the text can be freely recited in its own rhythm and shape. If this note alone is used, the effect soon becomes, in the strict sense of the word, monotonous. Therefore the music adopts the natural tendency of the voice to rise up to its reciting note at the beginning and to drop down from it at the end of the phrase. Thus arises the commonest chant-form of plainsong, consisting of (1) an intonation, (2) recitation, and (3) cadence, in each half-verse. The psalm-tones whether Gregorian or Ambrosian take this shape; and the form is capable of more or less elaboration for the psalms. The Gregorian tones are very simple; more elaborate forms of them are used for the Gospel-canticles; and still more developed forms for the Introits. A limit is naturally set to the amount of elaboration either (a) when whole psalms are to be sung at length, or (b) when they are to be sung by the whole congregation. When, however, select verses only are sung, and are sung by trained singers, there is far more scope for elaboration; and the developed responds used both at Mass and at the Choir-office exhibit this chant-form in a highly ornamental shape.

The chief development occurs in the Cadences. In its simplest form the musical cadence affects only the last syllable, e.g. there is the drop of a minor third. Next it concerns the last two syllables. These two simple cadences are familiar, even to those who do not know the Gregorian tones, from their being used in the Versicles and Responses of the Prayer Book. The more elaborate cadences naturally followed the "cursus" used by Latin prose-writers of the best, or at any rate, the most formal, style. In the responds a five-syllable cadence is constantly in use, and often in a highly decorated form.

All this music arises out of the recitation of psalms. For the purpose of declaiming the lessons of Scripture only the simpler inflexions were used; and the same is true of the prayers or collects, except a few which are of exceptional solemnity such as the "Preface" or the Lord's Prayer, as used in the consecration prayer at Mass; or the Hallowing of the Font at Baptism.

Antiphons.—Next to be considered is a totally different way of beautifying the recitation of psalms or other prose texts. Instead of elaborating the chant itself there was interpolated between the verses a suitable refrain. These refrains came to be known as "antiphons"; and thus side by side with the older method, which came to be called "responsorial" from the responds which represented it at its fullest development, there arose the newer "antiphonal" method. The former music developed from recitation, and even in its most elaborate forms in more or less degree it hung round a reciting note. The antiphons were purely melodic and the method had its quality and meaning determined,

not by reference to a "dominant" reciting-note, but to the "final" note on which it ultimately came to rest.

Antiphonal music underwent modification and development just as the responsorial music did. Its relation to the psalm altered; the singing of the refrain after each verse survived mainly in processional use. In choir offices the refrain was dropped so that it was sung only at the beginning and end of the psalm, or else in a curtailed form at the beginning and in full only at the end. In the psalmody of the Mass the opposite form of abbreviation was adopted. For at the Introit and the Communion the psalm became restricted to only one or two verses, and at the Communion it ultimately disappeared altogether, leaving the Antiphon alone.

Some antiphons composed on a large scale arose independently of any connection with a psalm. These were used especially in processions. Others retained the idea of a psalm-verse, but utilized for such verses not the normal psalm-tones, but independent melodies, perhaps as elaborate as the psalm itself. Such antiphons especially prevailed at the Offertory in the Mass.

The greater part of the classical Gregorian plain-chant falls into one or other of these two classes. The amount of elaboration depended mainly upon two considerations (1) the importance of the occasion; and (2) the capacity of the singers. A great festival or a specially dignified part of the service demanded richer treatment: and the trained singers undertook more difficult music than the congregation, the soloists than the choir generally.

The Gregorian Music.—The *Cantilena Romana*, Gregorian chant proper, is thus a body of music, purely vocal and ecclesiastical, evolved by the Papal choir in the course of the fifth and sixth centuries. This was codified in the time of St. Gregory (c. 540–604) (q.v.) and stands as the basis of all the Gregorian Music. The Milanese tradition was similar but less artistic. It is called "Ambrosian" (see AMBROSE, SAINT) but the term has no historical significance as the term Gregorian has. A comparison of these two families of plain-chant brings out clearly the comparative crudity of the Ambrosian tradition as distinct from the artistic balance and delicate finish of the classical Gregorian chant. The same is true also of such other specimens of Western ecclesiastical chant as are known. The Gregorian reform marks the close of a golden age of classical monody. The middle-ages subsequent to St. Gregory produced nothing so good; and the later part of them while producing only little and decadent plainsong depraved also the form of the classical tradition.

Something more must be said to describe the contents of the Gregorian *corpus* and also to explain the musical theory which lay behind it. The music covers the whole set of services of the Roman rite, but principally the Mass and the series of daily Choir Services. At the Mass some of the things sung are invariable, while others change according to the Sunday, or Festival, or occasion generally. The unchanging elements are chiefly the *Kyrie*, *Credo*, *Sanctus*, *Agnus dei*, and *Gloria in excelsis*. For these the old tradition provided little or no change of music; and what there was followed very simple lines suitable for congregational singing. The variable elements were principally the Introit-psalm, the Gradual-respond, the Offertory-antiphon and the Communion-antiphon. The Gradual was at times replaced or supplemented by an Alleluia with a Verse attached to it, or by a Tract. The Alleluia belonged specially to festive seasons and occasions, the Tract to penitential. Neither of these falls exactly into either of the two chief categories responsorial and antiphonal. The Tract is a very ancient but elaborate type of the developed psalmody; the Alleluia was an innovation which came in towards the end of the classical period, and extended beyond it into the "Silver Age" when little else was being composed.

For the choir-offices there was provided a large number of antiphons to go with the psalmody, and a considerable number of responses which mainly served as interludes between the lessons at Mattins. When hymnody began with St. Ambrose it was taken up and incorporated into the services by the monks; but Rome was for a long time too conservative to admit hymns. The plain-song hymn-tunes are, in the nature of the case, more definitely metrical than the other music: but they retain a considerable

freedom of movement, and are not "measured," like modern hymn-tunes.

Underlying Musical Theory.—The musical theory which lies behind this music is based on a series of eight scales or Modes. It uses the old diatonic scale of the Greek theorists (equivalent to the white notes of the pianoforte with the addition of B), but the modes themselves are different from the old Greek modes, and the use of the old Greek names only leads to confusion. The eight-mode system was probably the same as the *ὀκτώηχος* which underlies the Eastern church music; but the origins are obscure alike in East and West. The scheme seems to go back at least to St. John of Damascus (c. 750); but it is known in the West only in theoretical treatises derived through the Byzantine teachers at the court of Charlemagne at the end of the eighth century.

The eight modes are really four pairs, each pair being founded on the same note, the one scale (called Authentic Mode) being an octave ranging above the foundation or final note, the companion (called Plagal) being an octave ranging above and below it.

First	}	A BCD EF G a bc d
Second		
Third	}	BC D EF G a bc d e
Fourth		
Fifth	}	C D EF G a bc d ef
Sixth		
Seventh	}	D EF G a bc d ef g
Eighth		

Each of these pairs has a character or tonality of its own, dependent upon the position which the semitones have in the scale. None is similar to the major or minor key of modern music. It is this tonality which gives the special character to plain-song melody. Some theorists have reckoned twelve or even fourteen Modes; but this is unnecessary. So far as pitch goes, the range of two octaves covered by the eight modes is adequate; and so far as tonality is concerned, the new modes would be only the same as the first four or six over again with the Bb used instead of B. (For further discussion of the Modes see HARMONY.)

This modal theory does not fully account for all the procedure of the classical plain-chant (practice always surpasses theory): but these eight modes are clearly the foundation of this music, whether responsorial or antiphonal.

In the middle ages the *cantilena Romana* was handed on by tradition from St. Gregory's days; in the ninth century it was recorded in the notation reames. The notation on a staff which began a couple of centuries later, while it fixed accurately the pitch of each note, failed to reproduce the rhythmical delicacies which the earlier notation had recorded. Hence the recent renaissance of classical plain-song has been based on a return to the reames, as interpreted by the subsequent tradition.

The revived interest in music of the Carolingian era stimulated composition, which had been long in abeyance. Not only new music for new feasts arose, but fresh settings of the "Ordinary" (fixed elements) of the Mass. While the old music was preserved, it was padded out with new and inferior interpolations called by the generic name of "Tropes." These had their day and pervaded all the church music for a century or more; but then they went out of fashion, leaving only two considerable legacies, (a) a further series of settings of the "Ordinary," (b) the new form of rhythmical, or (later) metrical, poem called Sequences or Proses. These survived in considerable numbers down to the sixteenth century, but at the present time only a few are in use.

Modern Revival.—The rise of the art of harmony beginning from the eleventh century, diverted attention from the monody of plain-chant, and part-singing had the effect of "measuring" the music so that it fell into regular time and was no longer free or "plain." Under these influences the old plain-song was progressively debased and as harmonized music went up, plain chant went down. Not until the nineteenth century did this degradation cease. The efforts then made in various quarters to recover alike the true rhythm and tonality of the old music have culminated in the work of the Benedictines of Solesmes and their

followers, and in the revival which has produced the new Vatican Gradual and is producing by degrees a restored Antiphonal as well. With the recovery of the music has come a new insistence upon its use and study, as being the official music of the Roman church. (W. H. F.)

PLAINTIFF: see PRACTICE AND PROCEDURE.

PLAINVIEW, a city of northwestern Texas, U.S.A., 270 mi. W. by N. of Fort Worth, on the south plains of the "Panhandle" at an altitude of 3,370 ft.; the county seat of Hale county. It is on federal highways 70 and 87, and is served by the Santa Fe and the Fort Worth and Denver railways; also by air. Pop. (1950) 14,044; (1940) 8,263 by federal census. It is the trade centre of 5,000 sq.mi. of farming land, with more than 12,500 irrigation wells in the territory, raising chiefly wheat, vegetables, dairy products and grain sorghums. The Texas Panhandle-Plains dairy show is held there annually. The site for the city was surveyed in 1887. The settlement remained a trading post for the cattlemen who occupied the entire region until the railway reached it in 1907, and it was incorporated as a city. Farming began to displace ranching about 1915, and the cultivation of cotton began in 1918.

PLAMINKOVÁ, FRANTISKA (1875- ?), Czech leader of women, was born in Prague. Her father and more distant parental ancestors had all been interested in politics; her mother was a gifted singer and a great reader. Frantiska became a teacher; she then took up higher training at the University of Prague and travelled widely. In 1903 she founded the Women's Club of Bohemia and agitated for woman suffrage; she joined the Czech radical party and was elected member of the Prague city council on which she served for six years. While president of the Teachers' League of Czechoslovakia, she founded in 1923 the National Council of Women and was active in international work for the enfranchisement of women. In 1925 she became a senator of the Czech state—the first woman to attain that post—and was made a member of its finance committee. She organized a union of the women delegates of the different parties to support legislation of special interest to women.

Her active political life left little time for writing; but she published some pamphlets and articles, notably, in 1920, "On the Civic Equality of Women" and in 1924 on "Woman in a Democracy." When the Germans moved into Prague, she refused to leave. She died in a nazi concentration camp during World War II.

PLANCK, MAX KARL ERNST LUDWIG (1858-1947), German physicist, whose quantum theory is regarded as one of the great scientific contributions of modern times, was born at Kiel on April 23, 1858, the son of Johann Julius Wilhelm von Planck, a legal scholar. He studied at the universities of Munich and Berlin, and was awarded his Ph.D. degree at Berlin in 1879.

At Berlin his interest was turned toward black-body radiation by Gustav Kirchhoff, who had carried on some theoretical investigations in this field. Planck served five years as an assistant at the University of Munich, and then became a professor of theoretical physics at Kiel. In 1889 he went to Berlin as the successor of Kirchhoff, and remained there until he retired from teaching in 1926.

Planck devoted himself to the study of thermodynamics, and particularly to the investigation of radiation from black bodies. He observed certain phenomena in radiation that could not be explained on the basis of classical Newtonian physics. In 1900 he announced his important discovery in a paper, "Zur Theorie des Gesetzes der Energieverteilung im Normal-Spektrum" (On the Theory of the Law of Energy Distribution in a Normal Spectrum), and later expanded his theory. He found that energy is not a continuous entity, but comes in discontinuous small bundles or "quanta." These quanta are not all of the same size but vary with the frequency of the radiation of which they form a part. The study also disclosed a universal constant of nature, called h , and since known as "Planck's constant"; it showed that each quantum of radiant energy is equal to this constant, times its frequency. This constant has the value $6.6252 \pm 0.002 \times 10^{-27}$ erg sec.

Planck's quantum theory became the foundation for great ad-

vances in scientific knowledge. Albert Einstein expanded the theory and used it in developing his theory of relativity. Niels Bohr, the Danish physicist, employed the quantum theory to explain the known facts of radiation emitted by atomic structures. Planck's findings provided science with a key to the universe within the atom, a world in which nothing seemed to happen in the expected way in Newtonian physics. His constant came to be used in almost every mathematical description of the atomic realm, and the basis of the science of quantum mechanics (*q.v.*).

Planck won many scientific honours and gained wide acclaim during his lifetime. In 1918 he won the Nobel prize in physics for his discovery of elemental quantum. He was elected a foreign member of the Royal Society of London in 1926, and three years later he was awarded the society's Copley medal. He was an honorary member of the American Physical society. On his 70th birthday in 1928 Pres. Paul von Hindenburg presented him the silver eagle shield of the German reich. In 1930 he was appointed president of the Kaiser Wilhelm Society for Scientific Research, one of the highest academic posts in Germany.

After his early discoveries Planck did no further pioneering work, but he continued to be active long after his formal retirement from teaching. He remained in Germany during the Nazi period, but he openly opposed some of Hitler's policies. He appealed personally to Hitler to put an end to the Jewish persecution. In 1935 he was removed from the presidency of the Kaiser Wilhelm society. One of his sons was executed because he was suspected of complicity in the unsuccessful attempt to assassinate Hitler on July 20, 1944. Max Planck died at Göttingen, Ger., on Oct. 3, 1947.

Planck's works include *Vorlesungen über Thermodynamik* (1897); *Vorlesungen über die Theorie der Wärmestrahlung* (1906); *Einführung in die theoretische Physik*, 5 vol. (1916-30); *Das Weltbild der neueren Physik* (1929); *Treatise on Thermodynamics*, 3rd ed., Eng. trans. by Alexander Ogg (1927); *Introduction to Theoretical Physics*, 5 vol., Eng. trans. by Henry L. Brose (1932-33); *Where Is Science Going?* prologue by Albert Einstein, Eng. trans. by James Murphy (1932); *Philosophy of Physics*, Eng. trans. by W. H. Johnston (1936).

(See also QUANTUM MECHANICS.)

See *Scientific Autobiography and Other Papers*, with a memorial address on Max Planck by Max von Laue, Eng. trans. by Frank Gaynor (New York, 1949; London, 1950).

PLANCIUS, LUCIUS MUNATIUS, Roman soldier and politician, who took an important part in establishing the empire under Augustus. He served under Julius Caesar in the Gallic and civil wars. After Caesar was assassinated in 44 B.C., Plancius joined the forces of Mark Antony. He was consul with Lepidus in 42. He abandoned Antony in 32 and sided with Octavius in the final struggle for power. On Plancius' motion in 27, the senate conferred the title of Augustus on Octavius.

PLANE. The simplest definition of plane given by the Greek geometers is that of Heron of Alexandria (c. 200): a surface "such that if a straight line passes through two points on it, the line coincides wholly with it at every spot, all ways." Crelle (1834) defined it as the surface containing all the straight lines (throughout their entire lengths) passing through a fixed point and also intersecting a straight line in space. (For plane, a tool, see EDGE TOOLS.)

See H. Schotten, *Inhalt und Methode des planimetrischen Unterrichts* (Leipzig, 1890, 1893); Sir T. L. Heath, *The Thirteen Books of Euclid's Elements* (1926). (See also SURFACE.)

In botany, plane is the common name of a handsome tree known botanically as *Platanus orientalis* (family Platanaceae), a native of Greece and western Asia, a favourite shade-tree of the Greeks and Romans, introduced by the latter to southwest Europe. It is one of the most successful trees in London and other large industrial cities; the smooth face of the leaf is easily washed by rain; and the periodical peeling of the bark also serves to get rid of surface deposits of soot, etc. It is a large tree with widely spreading branches and alternate, palmately five-lobed leaves, resembling those of the sycamore maple in shape, but hairless and of a brighter green. The bud in the leaf axil is protected during its development by the hollow base of the leaf

stalk, which lifts off like an extinguisher when the leaf falls in autumn. The minute, unisexual flowers are borne in dense pendulous heads, which contain either male or female flowers; the small one-seeded nutlets, each bearing a tuft of long silky hairs, are densely crowded in a ball, from which they gradually separate in drying, and are readily carried by the wind.

A variety of forms are known in cultivation; var. *laciniata* has very deeply much divided leaves, and var. *variegata*, variegated foliage. The London plane, *P. acerifolia*, features three-lobed

PLANE (PLATANUS ORIENTALIS), SHOWING BRANCH WITH FRUITS. A. BRANCH WITH DROOPING FEMALE HEADS WHICH ARE WIND POLLINATED

leaves. Several authorities regard this as a natural hybrid (*P. occidentalis* × *orientalis*) rather than as a distinct species. *Platanus occidentalis*, an allied species, is a native of the United States, being most abundant and growing to its largest size in the basin of the lower Ohio and the Mississippi rivers. It was introduced into England early in the 17th century, and is occasionally met with in western and central Europe; it is known in America as sycamore (*q.v.*) and buttonwood. It differs from *P. orientalis* in its less deeply lobed, more leathery pubescent leaves and in the usually solitary balls of fruit. Both the native sycamore and the London plane are extensively planted as orna-

mental trees in the eastern United States. The California sycamore (*P. racemosa*) and the Arizona sycamore (*P. wrightii*), of the extreme southwest, are much smaller than the eastern species.

PLANER: see MACHINERY AND MACHINE TOOLS; WOODWORKING MACHINERY.

PLANET. The term "planet" was applied in the ancient Ptolemaic or geocentric astronomy to the seven heavenly bodies which were observed to change their places as projected against the background of the so-called fixed stars. These bodies were the sun, the moon, Mercury, Venus, Mars, Jupiter and Saturn, all of which were supposed to revolve around the earth. In the modern or heliocentric astronomy (taught by Aristarchus of Samos in the 3rd century B.C. but forgotten or neglected till revived by Copernicus in the 16th century A.D.) it is applied to all dark and opaque bodies in revolution round the sun, and the number of such bodies known has been greatly increased by successive discoveries. In 1781 William Herschel discovered Uranus. In 1801 Giuseppe Piazzi discovered Ceres, a small planet revolving between the orbits of Mars and Jupiter and the first of a great host of small bodies known as minor planets or asteroids; while in 1846 Neptune was added to the list of major planets following on the mathematical work on the unexplained irregularities in the motion of Uranus by Urbain Jean Joseph Leverrier and, independently, by John Couch Adams (see NEPTUNE). In 1930 a yet more remote planet was found at the Flagstaff observatory near the position predicted by the late Percival Lowell. It was named Pluto.

Most of the major planets possess moons or satellites. Neptune is known to possess 2, Uranus 5, Saturn 9, Jupiter 12, Mars 2 and the earth 1.

Distances of the Planets.—An empirical rule expressing the planetary distances from the sun was discovered by Titius of Wittenberg in the 17th century and later brought into notice by Johann Bode. If a series of 4's be written down, and 3 be added to the second, 3×2 to the third, 3×2^2 to the fourth, and so on, the sums of the numbers are 4, 7, 10, 16, 28, 52, 100, 196, 388, 772, etc. Division of these numbers by 10 shows fair agreement with the actual mean distances up to Uranus (see Table I), provided that the figure 2.8 is thought to represent the mean position of the asteroid ring. The success of representing approximately the first seven planetary distances by the Titius-Bode rule is not remarkable, since it was accomplished with five parameters (the three

TABLE I.—Principal Elements of the Orbits of the Major Planets for the Epoch 1956, Jan. 1. G. M. N.

Planet	Symbol	Mean distance from sun in		Eccentricity	Inclination	Period of sidereal revolution*

constants 4, 3 and 2 and the two rules, of putting the exponent of 2 at $-\infty$ for Mercury and of starting the regular count at Venus with the exponent 0). Furthermore, the rule fails for the major planet Neptune. The modern equivalent is to consider the planetary distances as a rough geometric progression, i.e., the radius of each orbit differs by roughly a constant factor from its neighbour. Actually, the factor varies from 1.4 to 2.0 (not counting Pluto, see below). It appears to have been determined largely by the local density of the solar nebula from which the planets formed.

Orbits and Phases of the Planets.—From the observations of Tycho Brahe, the great Danish observer, Johann Kepler deduced the following three great laws of planetary motion:

(1) The planets move in ellipses with the sun at one focus. Hitherto it had been believed that the celestial motions took place in circles, the circle being the perfect geometrical figure.

(2) The straight line from the sun to a planet (radius vector) passes over equal areas in equal times. The importance of this law was that it involves a continually varying rate of motion, which was also contrary to accepted beliefs at the time. To maintain the equal description of areas in unit time a planet must travel faster in the neighbourhood of perihelion where the radius vector is at a minimum than near aphelion where it attains its maximum value.

(3) The squares of the periodic times (the times required for the orbital revolutions of the planets) are proportional to the cubes of the mean distances (the semimajor axes of their orbits). This is known as the harmonic law and defines the relationship between a planet's orbital motion and its distance from the sun.

From these laws of planetary motion Isaac Newton deduced his law of universal gravitation which has achieved such remarkable success and prepared the way for Albert Einstein's relativity theory.

The dimensions, form and aspect of a planet's orbit as well as the position of the planet in the orbit at any time are defined by six quantities known as its elements. These are:

(1) Half the major axis, or mean distance (generally denoted by *a*). This defines the size of the orbit and also the period (*P*) by means of Kepler's third law, above.

(2) The eccentricity (*e*) or the ratio of the distance of the sun from the centre of the orbit to the mean distance. This defines the shape of the orbit.

(3) The inclination (*i*) of the orbit plane to the ecliptic, i.e., to the plane of the earth's orbit.

(4) The longitude of the ascending node (Ω), i.e., the direction at the sun of the point on the orbit (measured from the vernal equinox or "first point of Aries") at which the planet crosses the ecliptic from its south to its north side. This defines the aspect of the orbit.

(5) The longitude of the perihelion ($\tilde{\omega}$). This defines the direction of the major axis in the plane of the orbit.

(6) The longitude (*L*) of the planet at the epoch or time (*T*) of the planet's perihelion passage. The elements *a*, *P*, *e* and *i* are given for the several planets in Table I.

Since the orbits of Mercury and Venus lie within that of the earth these two planets when observed telescopically will show phases similar to those presented by the moon. When on the far side of the sun, i.e., near the time of superior conjunction, each

PHOTOGRAPHS OF PLANETS

1. Venus, showing the phases and greatest range in diameter resulting from revolution about the sun in an orbit inside that of the earth. When passing between earth and the sun, the right side of Venus is completely encircled by a ring of light (lower right) due to sunlight reflected through the planet's atmosphere
2. Jupiter, 1936 (left) and 1938 (right), showing the great red spot and notable changes in the belts
3. Saturn. Various aspects of the planet and its ring system (1936-45)
4. Spectra of Jupiter and Saturn illustrating the rotation of these planets and the meteoric nature of Saturn's rings. (The white line drawn at $\lambda 4349$ shows how the spectral lines of Saturn would appear if the ball and rings rotated as a unit)
5. Mars, showing its southern hemisphere in springtime (left) and in summer (right) with notable changes in the polar snow cap and the dark markings
6. Mars and its satellites, photographed Aug. 17, 1924. Phobos is close to the planet, at the left. Composite photograph right; Deimos is fainter and farther from the planet, at the left. Composite photograph

of them will appear like a small full moon. As the angle earth-planet-sun increases, a proportionally diminishing fraction of the illuminated surface will be presented to view; and when the angle reaches 90° , the planet will appear half-illuminated like the moon at first quarter. Following this, a crescent form of steadily diminishing breadth will be assumed as the planet moves toward inferior conjunction, at which point it passes between the earth and the sun. Subsequently to this, the phases described will be repeated in the reverse order up to superior conjunction when the planet will again be "full." The phases of a planet revolving outside the earth's orbit differ from those of Mercury and Venus in as much as the angle earth-planet-sun can never increase to 90° . Thus Mars, although at times presenting a gibbous aspect like an eleven or twelve days' old moon, is always more than half illuminated. In the case of Jupiter the defect of illumination is so small as to be almost imperceptible. In the cases of the planets revolving outside Jupiter the phase is quite imperceptible even in powerful telescopes. The variations in apparent diameter and brightness will, of course, also be small in the cases of the remoter planets.

Planetary Atmospheres.—There are striking physical distinctions between the giant planets, Jupiter, Saturn, Uranus and Neptune on the one hand and the terrestrial (or earthlike) planets Mercury, Venus, earth, and Mars on the other hand. The planets of the first group, besides being much larger and more massive than the terrestrial planets, show no fixed permanent surface features and are of very low density. The density of Saturn is actually less than that of water. The terrestrial planets range in density from 4.1 that of water for Mars to 6 for Mercury. Both Mars and Mercury show fixed markings on their surfaces. Impermanent clouds, often arranged in roughly parallel belts, can be seen in the atmosphere of Venus. The masses and, consequently, densities of those planets possessing satellites are derived with great precision from the distances and periods of their satellites by an application of Kepler's third law. The masses of Mercury and Venus are deduced from their gravitational disturbances on the motions of other planets, whereas the mass of Pluto has proved too small to be so determined.

The knowledge of the mass and diameter of a planet permits the calculation of the attraction of gravity at its surface, g , and the velocity of escape, v_e , which is the limiting velocity which a particle must exceed if it is to escape from the planet. The computed values of g and v_e are found in Table II. Note that for planets of different density, ρ , the values of g and v_e are not proportional; the reason for this is found from the definitions ($g = Gm/r^2$; $v_e = \sqrt{2Gm/r}$; $m \sim r^3\rho$; m and r are the mass and radius of the planet and G is the constant of gravitation).

The rate of escape of molecules from the uppermost layer of a planetary atmosphere (called *exosphere*) depends not only on v_e but also on the temperature and the molecular weight of the gas: both a high temperature and a low molecular weight will increase the molecular velocities and therefore the fraction that exceeds v_e . The exosphere temperature depends on the strength of the solar radiation received (which may be computed for each planetary distance) as well as on the atmospheric composition. Thus for each planet a prediction may be made as to which gases, if any, will be retained near its surface. It is found that Jupiter and Saturn will retain even the lightest gases, hydrogen and helium, for astronomically long intervals of time (several billion years or more); while the earth and Venus will lose these light gases but will retain all heavier ones. Mars will retain carbon dioxide, argon, and probably nitrogen, but may lose oxygen (which, because of its strong ultraviolet absorption heats up exceptionally).

The observations support these conclusions in a general way. The spectra of the giant planets show strong absorption bands due to methane and ammonia, identified by Rupert Wildt in 1932 and confirmed in detail by T. E. Dunham. Uranus and Neptune show weaker absorptions besides, due to molecular hydrogen and probably HCO, both discovered by Gerard P. Kuiper in 1949 and identified by Gerhard Herzberg in 1952 and 1955, respectively. Helium causes no visible absorptions of its own, but G. Herzberg, from laboratory experiments, found evidence that the planetary spectra of hydrogen show pressure effects attributable to helium. Kuiper

discovered methane on Saturn's satellite Titan in 1944, but no ammonia, which would have frozen out; and concluded that Pluto and Neptune's satellite Triton may have tenuous atmospheres, which would account for the rather strong ultraviolet reflectivity of these bodies; so far no specific molecular absorptions have been found.

On the earth hydrogen and helium are constantly being replenished in the atmosphere, by the photodecomposition of water vapour in the upper atmosphere and radioactive decay in the crust, respectively. The other gases in the atmosphere, though of secondary origin (*i.e.*, due to degassing of the crust), are not now being lost. In pregeologic time, however, there must have been very severe losses to the protoatmosphere as is shown by the very low relative abundances of the inert or noble gases, neon, argon, krypton, and xenon. These gases must always have been part of the atmosphere and are therefore of great importance in tracing its early history. On Venus a dense atmosphere of carbon dioxide was discovered by Walter S. Adams and T. E. Dunham in 1932; but water vapour and oxygen could not be detected. Mars has an atmosphere totalling about one fifth in mass of the terrestrial atmosphere, as determined from its light-scattering power; but Adams and Dunham found the oxygen and water-vapour content too small to be detected spectroscopically. With a newly developed infrared detector, Kuiper discovered carbon dioxide in 1947 and also that the Martian polar caps were water snow, not carbon dioxide snow. Traces of water vapour must therefore be present on Mars; the frost point is estimated to be about -75°C . from the extent of the polar caps and the computed ground temperatures. Most of the martian atmosphere may be nitrogen, with some radiogenic argon added. Mercury has no perceptible atmosphere, the upper limit being 0.3% of our atmosphere, according to A. Dollfus. The moon may have a trace, about 10^{-13} terrestrial atmospheres, as appears to follow from certain radar observations. Such an amount is about what would be expected from the rate of argon production in the lunar crust, coupled with the expected rate of escape to space from the lunar exosphere.

Planetary Surface Temperatures.—The heat radiated to space by a planet is nearly in balance with that fraction of the solar radiation which the planet absorbs. For the terrestrial planets the heat flow from the interior is so small that the balance is precise; for Jupiter and Saturn the heat flow from the interior is not negligible, as is shown by the "spontaneous" disturbances in their cloud covers. Nevertheless, even for these planets there will be approximate balance. Now the heat loss by radiation per unit area is proportional to T^4 , while the gain by absorption per unit area is proportional to $(1-A)a^2$, where A is the planetary albedo and therefore $(1-A)$ the absorbed fraction of the received solar radiation; while a is found in Table I. For a surface placed at right angles to the solar rays one finds, from the known "solar constant," the equilibrium radiation temperature to be $394^\circ \times (1-A)^{1/4} / a^{1/2}$, counted from the absolute zero. For a rapidly rotating planet the solar radiation is spread over an area four times that of the cross section of the beam, and therefore the temperature will be $4^{1/4} = \sqrt{2}$ times lower than for a "normal" surface. The computed mean radiation temperatures for rotating planets are found in Table II. They apply to whatever atmospheric or surface layer is most effective in the radiation to space. Note that this layer on Venus is no warmer than that on the earth, owing to the high albedo. For planets with dense atmospheres and condensation products, the surface temperatures must be higher than the radiation temperatures owing to the greenhouse effect. For the earth the difference is about 30°C . and the difference is not constant, as is shown from the occurrence of ice ages.

Planetary temperatures may be measured by placing a thermocouple or a Golay cell at the focus of a large reflector. Such work has been done especially at the Mt. Wilson and Lowell observatories. The measures are hampered by the variable amounts of water vapour in our atmosphere but the region from 8 to 14μ is comparatively free and is used. This means that temperatures much below 300° absolute are not readily accessible. Results on the giant planets are therefore rather in the nature of upper limits; furthermore, they are strongly affected by particular molecular

TABLE II.—Physical Constants Pertaining to the Major Planets

emissions in the 8-14 μ region, such as are due to ammonia. Thus, the measured temperatures of Jupiter and Saturn are essentially the temperature at which ammonia vapour makes its appearance, about 130° absolute (−143° C.). For the terrestrial planets and the moon the results are more significant and good general agreement exists with the computed temperatures. Edison Pettit established the important result that the day and night sides of Venus are virtually at the same temperature, of 241° absolute (−32° C.), indicating rapid atmospheric convection between the two hemispheres. For the moon Pettit measured, among others, the temperature drop during a lunar eclipse, which led to a determination of the coefficient of thermal conductivity; from these data the lunar surface was found to be covered with a fine powder (probably caused by meteoritic impacts). For Mars the noon temperature at the equator was found to be about 0°–10° C., somewhat less, as it should be, than the maximum attainable for a normal surface exposed indefinitely, being 34° C.

Composition of the Planets.—The terrestrial planets are composed of silicates and metals, in varying proportions, as follows from their different densities. Mercury, though of small mass and therefore little compressed, is denser than the earth which, if uncompressed, would have a density of about 4.2. Mercury must contain about $\frac{2}{3}$ iron, and this suggests that the liquid core of the earth is iron also and not a high-pressure phase of silicates. Jupiter and Saturn are composed of about 80% and 60% hydrogen, respectively, according to William H. Ramsey, who suggested that Uranus and Neptune may be partly composed of metallic ammonium. All four giant planets must have earthlike cores at their centers, though more massive and more compressed than the earth, since these planets arose from protoplanets that were more massive than protoearth. Intermediate between the earthlike cores and the mantle of metallic hydrogen, Jupiter and Saturn may possess a shell of compressed ice, as was suggested by R. Wildt.

Origin of the Planets.—It is reasonably certain that the planets condensed from large gaseous clouds, or protoplanets, about 5×10^9 years ago; and that these protoplanets were essentially of solar or cosmic composition. Protoearth was some 500 times more massive than the present earth; proto-Jupiter about 20 times. The protoplanets appear to have segregated from a primeval nebula that surrounded the sun; the mass of the solar nebula was about 6% of the solar mass. The process of planetary formation appears to have been incidental to the formation of the sun itself, with the solar nebula consisting of the material that, because of its large angular momentum, stayed behind in the general contraction process. The protoplanets formed by gravitational instability within the nebula before the sun had completed its contraction and had become luminous. The temperature in the nebula at the time of break-up appears to have been exceedingly low, some 40° absolute, which, because of the abundance of snows, greatly speeded accretion. Later, when the sun got bright, its radiations drove off the gaseous envelopes or protoatmospheres of the terrestrial planets and left them virtually bare. It also greatly reduced the masses of the giant planets. These gigantic mass losses had several indirect effects, such as great increases in the inclinations of the planetary equators (see Table II); the loss of satellites to interplanetary space (probable formation of Pluto from Neptune, and Hidalgo and the Trojan asteroids from Jupiter); and the formation of a dozen irregular satellites (being lost satellites that were recaptured).

The minor planets or asteroids appear to have originated as condensations in a tenuous part of the solar nebula between proto-Jupiter and proto-Mars. Gravitational instability could not occur in this tenuous ring so that not one large condensation (or planet) developed but instead innumerable smaller condensations formed by accretion, much like snowflakes in a cloud. A similar tenuous ring must originally have

existed outside proto-Neptune, which appears to have given birth to the comets. The dimensions and compositions of the asteroids and of the comets are in general accordance with the predictions based on this theory.

Habitability of the Planets.—The giant planets appear to have solid surfaces only at great depth, as a result of excessive pressures (over 100,000 atmospheres); while the atmospheres are strongly reducing (large excesses of free hydrogen). No life as we know it could exist there. The moon and Mercury are unsuited for life due to lack of atmospheres. Venus must have produced some free oxygen or its atmosphere would be expected to contain carbon monoxide as well as carbon dioxide, since both are produced by terrestrial volcanism. This oxygen originated probably from photolysis of water vapour, not from organisms. The apparent absence of appreciable quantities of water and oxygen, and the high carbon dioxide content, make Venus an unlikely place for life to have developed.

In addition, the greenhouse effect of the Venus atmosphere is probably very large, with the surface temperature exceeding the boiling point of water. The Venus cloud cover is probably composed of a photochemical product of CO₂ and CO, such as C₃O₂, polymerized into particles that may be about one micron in diameter.

The case of Mars is distinctly different. This planet possesses an atmosphere containing carbon dioxide in quantities similar to the earth, as well as traces of water vapour, and probably nitrogen and argon. Photosynthesis is therefore possible. The daily temperature range, while larger than in the terrestrial deserts, is not extreme. The night temperature may reach −80° C. or −100° C., but would not be fatal to some organisms, as lichens, occurring on the earth. In fact, some terrestrial lichens, if transplanted to Mars, might survive.

The dark areas on the planet bear some resemblance to those on the moon and on Mercury, and are therefore likely to be extensive lava fields. The delicate green and brown colours occasionally observed on these dark areas may represent a hardy type of vegetation partially covering these lava fields.

PLANETARIUM is the name given to an arrangement, made by Carl Zeiss of Jena, for producing an artificial sky. By optical methods images of the sun, moon, planets and stars are projected on a large hemispherical dome and by mechanical and electrical means the apparatus can be revolved so as to show the principal motions. The name planetarium is apparently given because of the success with which the apparent motions of the planets among the stars can be shown; but the apparatus makes possible the representation of many other astronomical phenomena.

For several centuries orreries have been used to demonstrate the motion of the planets round the sun according to the Copernican system. Perhaps the best arrangement of this kind is in the German museum at Munich where the observer can be carried in a cage which is moved in a path representing the earth's orbit. By means of a periscope he can look out on the motions of the other planets and at the stars of the zodiacal constellations shown

on the wall by means of small electric bulbs. But it is impossible in a model of this nature to make the relative distances correct and thus to get the proper alignment of the various bodies. When this instrument was ordered from Zeiss in 1913 it was suggested that another astronomical model might be made depicting the heavens as actually seen from the earth and it was suggested that the heavenly bodies might be represented by electric bulbs fixed or moving on a rotating dome. This suggestion, however, was soon discarded in favour of another, by Dr. Bauersfeld, in which the images of the bodies were projected optically on a fixed dome. The resulting apparatus has been a great success. It is found that when a dome 50 ft. or more in diameter is used, the appearance is extremely like that of the actual sky. For the stars it is merely necessary to have the projector mounted so that it can be rotated about an axis parallel to the earth's axis. For the sun, moon and planets small models, true to nature, are constructed. The angles between the orbit planes are allowed for and by the use of eccentric circular motion the elliptic motion is quite closely represented. For showing, say, the planet Venus, the model has pins representing Venus and the earth moving round the sun. A little projector is attached to the pin representing Venus and a linkage between the planets always directs the light away from the earth. Consequently, the image of the planet on the dome is in the correct position among the stars. The gearing is so arranged that the mean motions are accurately represented and only comparatively slight periodic errors affect the positions of the sun, moon and planets. The phases of the moon are shown by an occulting device.

The planetarium can be operated at varying speeds corresponding to the phenomenon to be demonstrated so that even such a slow motion as that of the precession of the equinoxes is within its range. To show the rising and setting of the heavenly bodies a day is compressed into an interval of from 1 to 4 min.; to show that of the planets the diurnal motion can be put out of gear and a year run off in intervals varying from 7 sec. to 4 min. The original model was made for one latitude only, but in later ones, by introducing an additional axis of rotation, the latitude can be altered at will. The stars are shown brighter than they appear in the sky—the eyes of the spectators coming from the daylight would otherwise take too long to be sensitive enough to see them. It is, of course, impossible to make the sun as bright as in nature but this has the advantage of enabling the stars to be seen in the sky along with the sun and thus demonstrate the motion of the sun among the stars.

With the planetarium the spectator can see in an hour or so motions which can be seen in the heavens only by years of watching. When a year is compressed into a minute or two the planets can be seen chasing one another about the sky, describing loops, advancing and retrograding, just as they do so slowly in nature. Great attention has been paid to details so as to make the apparatus as perfect as possible; e.g., the brightness of the objects is dimmed as they approach the horizon and the light is practically cut off as the star actually reaches the horizon. The date corresponding to the configuration can be projected on the dome as well as the names of the constellations, and by means of a luminous pointer a lecturer can point out objects of interest. Planetaria have for some time engaged popular interest in a number of German towns.

In the United States the first to be erected was the Adler planetarium at Chicago, but others are now to be found in Los Angeles, Calif., Philadelphia, Pa., New York, N.Y. and Pittsburgh, Pa. (J. JN.)

PLANING MACHINES rank in importance with the lathes and drilling machines, and cut various kinds of plane surfaces in metal. The principle is that of attaching the metal to a long table which slides truly upon a massive bed, so that by holding a cutting tool in a slide overhead, the material becomes shaved off as the table moves. The width of surface is treated by giving the tool a cross-traverse. The slide moves on a horizontal rail for this purpose, and the rail is adjustable up and down, two up-rights flanking the bed. Toolslides are often put on the faces of the up-rights as well, so that the sides of the work may be planed. Planing machines are of value both for big and small

articles; they may take one of the former and deal with it singly, or a whole string of small objects can be clamped in line on the table and surfaced off. (See also WOOD-WORKING MACHINERY; MACHINERY AND MACHINE TOOLS.)

PLANKTON is the name used for that great section of marine life which drifts under the influence of sea currents, to distinguish it from those organisms (the nekton) which can swim against the currents and those (the benthos) which are found attached to, and crawling on, the sea floor. Planktonic life is important because all animal life in the sea is ultimately dependent on it for existence. The great majority of planktonic organisms are microscopic plants and animals; by definition, the plankton also includes bigger organisms, even the largest jellyfish and the floating Sargassum weed. Little was known of any except the largest of them until, in 1845, Johannes Müller towed a small conical net of fine-meshed cloth behind a boat and collected a sample of the minute plants and animals. Many forms new to science were soon collected in this way, even in coastal waters, although it was not until 1872-76, when the "Challenger" expedition explored the great oceans of the world, that a real impression was obtained of the almost infinite variety hidden in the sea. In 1889 Victor Hensen (who first used the name *plankton*) led his special "Plankton expedition" to make a more detailed survey in the Atlantic; many others followed, the most recent being the series of "Discovery" expeditions to study the life of whales in antarctic waters. In 1902-08 the International Council for the Exploration of the Sea set an example of co-operation in research by arranging for its fishery program to include an international survey of plankton distribution in and about the North sea. Equally as important as all this work at sea was that done by the marine shore stations, of which those at Naples, Plymouth, and Woods Hole (Mass.) are among the most famous.

The Cycle of Life in the Sea.—Just as all life on the land is ultimately dependent on the sun for its existence, so it is also in the sea. Simple nutrient salts (phosphates, nitrates, etc.) are everywhere dissolved in minute quantities in the water together with carbon dioxide. With the aid of light energy from the sun's rays, the large seaweeds of the shores build these into the complex materials of their tissues. For this reason the seaweeds live only within reach of the sun's rays and, since they are normally attached, they can form only a fringe of vegetable life around the continents and islands. Again as on land the marine animals need their food in a complex form, ready-made either by plants or by other animals which themselves have fed upon plants. The seaweeds, however, are too few to feed more than a small proportion of marine animals, and most of these depend on the planktonic plants (phytoplankton). These plants float in countless millions in the upper layers of the water, buoyed by a variety of devices which lessen their density so that they remain in the sunlit zone. When the supplies of nutrient salts are sufficient, and the light and temperature adequate, they may double their numbers daily until in places the sea becomes coloured with them or even foul. They provide the food of the minute planktonic animals (zooplankton) which in their turn form the chief food supply of young fish; in their youngest stages the fish too may feed on the plants. Some fish, such as herring and mackerel, feed largely on plankton for the whole of their lives, as also do the whalebone whales. Other fish, as they grow, feed more and more on larger animals, either fish or animals which live on the sea floor, such as crabs and whelks. This life of the sea floor, in its turn, is fed by the rain of dead and dying plankton which is continually falling from the upper layers of the water. The whole system forms a network of feeding "chains," which, as the salts and carbon dioxide are returned to the sea by excretion and death, is seen to be part of an elaborate chemical cycle.

As the sunlight strengthens and penetrates deeper during the spring, the few green plant cells which have remained in the upper layers over the winter months begin to divide and spread through the waters, usually first near the coasts and then farther out to sea. The warming of the surface waters in late spring and summer sets up a boundary between the less dense surface water and the deeper layers which are still cool, so that chemical exchange between them becomes difficult. The phytoplankton con-

sumes most of the surface supplies of nutrient salts during its spring increase so that the phosphorus and nitrogen exist only in the plant tissues and in the animals which have fed upon them. Partly as a result of this consumption, and partly as a result of the "grazing" of the zooplankton, the green plants are normally scarcer in the summer; in their places develop smaller numbers of brownish cells (dinoflagellates) whose requirements of salts are much less. The zooplankton, however, has increased greatly, both by the reproduction of permanently planktonic animals and through the hatching of innumerable planktonic larvae of fish and bottom-living species. A little later these planktonic larvae take up their adult lives as swimmers or bottom-dwellers; their survival up to this stage has depended on the supplies of phytoplankton available to them.

Fish and other animals take their toll of the permanently planktonic animals which, by the autumn, are decreasing. The year is not over, however, for there is a second (autumnal) harvest in the sea. As the autumn storms develop and the sun's rays decline, the boundary between the light surface waters and the denser deep ones breaks down and the two layers can mix again, providing fresh supplies of salts to those waters still lighted by the sun. Another crop of green plants, not always the same kinds as in the spring, has a brief period of abundance before winter sets in. Usually, little plankton is to be found in the winter months, either plant or animal, but during this time the supplies of salts are redistributed and restored (following the continual processes of decay) by strong vertical and horizontal water movements.

The cycle just described is typical of temperate waters in the northern and southern latitudes; the seasons are similar even though the months are reversed. In higher latitudes the spring and autumn plant harvests are respectively later and earlier until in the polar regions they meet as one. In warmer waters neither is so prominent; the plant numbers at any time are far fewer but, with the possibility of reproduction over the whole of the year, the quantities available for animal food may still be appreciable.

Planktonic life is usually found in recognizable communities, taking the form of distinct patches in the sea. They are, how-

ever, by no means static; their natures and constitutions are continually changing, not merely because of the rapid rate of increase and decrease common to all small organisms, but also because of changes in their environment and the complex interactions between the organisms themselves. The proportions of prey and predator in the different food chains are never constant, and a change in one is rapidly reflected in others since the chains are parts of a continuous network. Feeding relationships are not the only ones whereby the organisms interact, for there must also be relationships depending on the plants' varying needs of the different nutrient salts. Another type of interaction is based on observations that many plankton animals (and some others) are relatively scarce where the plants are very numerous; the animals appear to avoid regions in which plant activity has been excessive.

The Kinds of Plankton.—There are representatives in the zooplankton of nearly every important group of animals from the fish downward, although only one major plant group, the algae, is found in the phytoplankton. The best-known members of the phytoplankton are the diatoms, unicellular greenish-brown plants enclosed in a transparent shell of silica. They range in size from forms like the long *Rhizosolenia styliformis*, just visible to the naked eye, to the minute species of *Nitzschia*. Many, like these, live as separate individuals, but others (e.g., *Thalassiosira*) are joined in chains; some forms have their shells drawn out into long hairs (e.g., *Chaetoceros*). Together they form the most conspicuous plankton plants and in places their dead have accumulated to give rise to large beds of "diatom ooze" composed mainly of the shells. They were long thought to be the chief food producers in the sea, but it is now known that far greater numbers of smaller algae, mainly green flagellates, may play a more important part. The flagellates are also unicellular and the most familiar are the brown ones (dinoflagellates); they are typical of the summer and produce much of the phosphorescence seen then (e.g., *Ceratum*, *Peridinium*, etc.). They build living tissue as the diatoms do but, by means of a pair of whiplike flagella, they can move and eat the very smallest particles of food as well. They are adaptive to environmental conditions, apparently changing their shapes gradually in response to changes in temperature, so that their varied forms have been used to dis-

tinguish water masses of different origins. The smaller green flagellates live wholly like plants, except for their locomotion by means of flagella; at certain seasons may be included with them in the phytoplankton the myriads of flagellated spores and germ cells released by larger marine plants. Most of the green flagellates are individual, but one form is familiar for its habit of living colonially in a gelatinous mass and is normally nonmotile. It is called *Phaeocystis*, and may at times be abundant enough to clog herring fishermen's nets, causing much trouble in cleaning.

The coloured flagellates, with their animal movements and plant nutrition, have been studied by both zoologists and botanists, but there are numbers of colourless ones which can be considered only as animals; a large and unusual one, *Noctiluca*, is another cause of luminescence on summer nights. Two more unicellular plankton groups, both related to amoeba but far more striking, are the Radiolaria and the Foraminifera. Both of these have elaborate skeletons and, following the deaths of the adults, these also have accumulated in such numbers over certain parts of the oceans as to give their names to distinctive oozes on the sea bed.

Most marine animal groups are represented in the plankton for a time by large numbers of eggs and larvae, and few of them are without at least one wholly planktonic representative. Among the most beautiful are the Ctenophores, Siphonophores and jellyfish (see MARINE BIOLOGY) as well as the medusoid larvae of the bottom-living coelenterates. Among the worms the arrowworm (*Sagitta*) is particularly important in plankton research; other worms provide their trochophore larvae and a number of wholly planktonic adults. The molluscs include whole groups which are planktonic. There are the pteropods (*Limacina*, etc.) which, by their cast shells have given a name to yet another type of ooze, and the heteropods (*Carinaria*, *Pterotrachea*, etc.); in addition there are the veliger larvae of many bottom-living molluscs. The pluteus larvae of the echinoderms are also prominent members of the plankton, although the pelagothurians are the only wholly planktonic echinoderms. Another group, closely related to the sea squirts, includes the salps and doliolids, with their barrel-shaped gelatinous bodies; they are wholly planktonic and, in coastal waters, may be valuable indicators of oceanic water. A related animal is *Pyrosoma*, which is luminescent, but found only in warm waters.

The Crustacea must be considered the most important members of the zooplankton. They have many kinds of planktonic

larvae (e.g., the zoea larvae of crabs); and one particular section, the planktonic copepods, plays in the sea some of the parts played by insects on land. Most of the copepods are less than one-eighth inch in length but they are among the most numerous animals in the sea, grazing down the phytoplankton and providing basic food for fish. There are many species, but the best known of them is *Calanus finmarchicus*, abundant round all the shores of the North Atlantic. The Euphausiids, with their serrated luminous organs, are another important planktonic section of the Crustacea. These are the chief food (krill) of the largest animals the world has known, the blue and fin whales. So dense are their swarms in antarctic waters that the whales can, by taking gulps of water and straining the plankton through their whale-bone, feed fast enough to grow within 2 years to sexual maturity and a weight of about 60 to 70 tons.

An early but most important discovery was made by G. O. Sars when he showed that most fish, including those of economic importance, have planktonic eggs and larvae; herring differ in laying their eggs on the sea bed but, on hatching, their larvae immediately drift into the upper waters. This discovery answered one of the early objections to the use of heavy trawls in fishing, for many fishermen had feared that by trawling they would ruin the spawning grounds of the fish.

Distribution and Movements.—There are few, if any, masses of water without plankton and, although the phytoplankton is necessarily limited to the illuminated layers, zooplankton has continued to be found (in gradually decreasing numbers but often increasing size) as new methods have made deeper sampling possible. Before the cruises of Wyville Thompson in the "Lightning" and "Porcupine" (1868-70) it had been thought that life was impossible in depths greater than 300 fathoms. These and later expeditions suggested that depth determined only the nature of the life and never prevented it. Whether on the bottom or free in the water, life at great depths is necessarily scarce, since it and all the animal life for perhaps five miles above it is indirectly dependent on the activities of the plants within a few metres of the surface. While there are many exceptions, it is general for transparent or pale blue animals to be limited to the surface layers, in contrast to the deeper occurrence of reds and violets; vivid scarlets and blacks are mainly to be found only in the great depths. The full reasons for this are ill understood, but they are likely to be associated with the manner in which light rays penetrate water, the red ones least of all and the blue ones most. More

FIG. 3.—COLLECTING APPARATUS

A typical plankton net, with throttling rope, is shown above. In the continuous plankton recorder, shown below, the plankton is collected between two bands of silk mesh driven by the propeller working through a gear box

astonishing is the abnormal development of the eyes in some deep forms and, often in the same animals, the elaborate structure of their luminous organs.

Light has been thought to play a major part in the regular vertical migrations which most plankton animals make each day. Usually they move upward as the light declines and downward again, sometimes over hundreds of feet, as the light strengthens in the morning. Many observations and detailed experiments have been made to uncover the processes resulting in this vertical migration. While light must almost certainly play a large part, some research has suggested the possibility of its interplay with other factors, such as a changing response to the effects of gravity, a daily rhythm in the need for plant food and reactions to slight changes in the acidity of the environment. Some plankton animals appear to vary in the range of their vertical migrations roughly in accordance with the extent to which they appear to avoid phytoplankton. One theory suggests that it is by descending for the daytime that the animals escape those products of plant activity which they appear, when viewed from above, to be avoiding. At night, when the plants' activities are changed, the animals migrate upward to feed. During vertical migration, the animals alternate between layers of water which often move at different speeds and directions; their horizontal positions are automatically changed, not only in relation to each other, but also in relation to the phytoplankton, from beneath which they tend to be removed.

Apart from the influence of light, it is probable that temperature is the chief governing factor in the distribution of the plankton. Many animal forms are to be found deeper during the summer months than in the winter. Others with a wide distribution may appear at the surface in polar waters, but live only in the depths of tropical waters, where a low constant temperature is maintained. Heat must be the controlling factor there, although light may have a part in the seasonal migration. Within the surface waters there are striking changes as one travels from the north, through the tropics and so to the antarctic. In contrast to the vast quantities of plankton in the higher latitudes the tropical waters are much more thinly populated; this may be a partial explanation of the distribution of the chief commercial fisheries. On the other hand, the tropics provide a wealth of variety which has made the plankton there a permanent source of wonder to marine biologists.

While some of the organisms are almost world-wide in distribution, most are limited by some factor or other so that each of the seas has its own particular combinations of life; and collections from different places, and also from different depths, can easily be recognized. Within them all, however, it is convenient to make another type of distinction, in which the saltiness of the water is important. The proportionate constitution of sea salts scarcely

varies over the whole sea, but their total quantity in relation to the water rapidly diminishes near the coasts and the polar ice masses, where the fresh water dilutes the sea. The coastal waters have their distinct types of plants and animals, usually termed neritic in contrast to the more widespread, but less abundant, oceanic plankton. The mixed waters between them in temperate and polar seas are among the richest in the world, for the oceanic waters provide large supplies of nutrient salts and large plant crops develop there each spring. Supplies of salts are also replenished by deep ocean currents upwelling against the coastal banks, so that phytoplankton flourishes there and the bottom life is abundant. It is in just such places that the largest trawl fisheries have been established. The interplay of oceanic and coastal waters is intensively studied for this reason, and an important advance was made when it was found that some of the larger and more typical planktonic forms (such as the species of *Sagitta*) may be used as easily recognizable indicators of the relative strengths and distributions of these waters in different years.

Methods of Collecting Plankton.—The commonest means of collecting plankton have changed little since J. Müller first towed his conical net at the sea surface. At the tail of his net he had a small glass tube into which the filtered organisms were washed and so preserved from damage. A net such as this may be used by any naturalist in local waters to add greatly to his enjoyment of the varied forms of life. The plankton nets used on the "Discovery" expeditions of 1924-39 were essentially the same, though developed and specialized for various purposes. The finest and smallest are of silk (up to 200 meshes to the inch) and long in proportion to the net opening so that the meshes provide as great a filtering area as possible; in place of glass tubes, they have small detachable metal "buckets" to collect the samples. Larger and coarser nets are made of stronger material and are used for the larger animals. Since the nature of the plankton varies greatly with the depth of water it has become essential, whether the net is used vertically or not, to know at what depth it has been fishing, and it is common for nets to be fitted with throttling ropes so that they may be opened and closed when desired. Series of such nets may be used together at various depths on one towing wire, being opened and closed by weighted "messengers" running down from net to net and operating trip mechanisms through which the throttles are worked. Such methods can be used only from specially equipped research ships working slowly from station to station, but they have provided the bulk of our knowledge of plankton distribution. They can be supplemented by pumping water through a flexible pipe and filtering the plankton on deck; this has the advantage of more complete control than when using nets, although delicate planktonic forms may be destroyed by the water pressure. For some purposes samples are best taken in a "water bottle" (see MARINE BIOLOGY) which can be closed or opened at will to collect a known quantity of water, perhaps with a temperature record, for chemical and biological analysis. This is suitable for small forms which easily pass the meshes of the finest silk; they may be collected into a small volume of water by centrifuging and then examined.

Two other instruments have been used in later years. One, the plankton indicator (mentioned below), collects samples on a disc of silk mesh placed at the end of a small tube; it is convenient for certain types of research and for commercial purposes. The other, the continuous plankton recorder, is a development of this for collecting continuous samples of plankton on a moving band of silk. It is so arranged that it may be loaded in a laboratory and handed to the officers of commercial ships for automatic collection and preservation of plankton while being towed between selected points on their routes; the machine with its record is then returned to the laboratory for analysis. With this apparatus continuous records of plankton can be obtained regularly over wide areas at a small cost; they provide standardized data for comparison with hydrological observations and the landings of fish.

Plankton and the Fish Supply.—Though the place of plankton in marine economy had been realized for some years, its practical applications were still only beginning to be developed in

the 1930s. Not until a wide knowledge of the types of plankton and their variations in abundance had been obtained could scientists begin to ask those questions which might give answers of commercial value.

A casual association of the herring with plankton had long been realized before detailed analysis of thousands of stomach contents showed it to be dependent on plankton throughout its life. Its fate immediately after hatching hangs on a supply of plant plankton; then, as it grows, it feeds on the smallest animals, and later on larger ones. Even when adult, the herring can get from the plankton alone those supplies of oil which seem to be necessary for its own reproduction, and make its flesh so valuable as human food. From late spring to summer, varying a little with the years, herring feed intensively on the copepods (and specially the large one called *Calanus*) and their growth rate depends on this supply of food. It is known that the success or failure of a fishery may be influenced not only by the abundance and distribution of the copepods, but also directly by the plants. Small samples of plankton were taken regularly over four years with the plankton indicator in waters fished by herring drift nets; each was analyzed and correlated with the numbers of herring caught in association with it. One of the resulting correlations showed the regular scarcity of adult herring in waters where the plants were very abundant; since this applied when the herring were scarcely feeding, there appeared to be a definite avoidance of such waters by them. In confirmation it was shown that dense patches of diatoms or the colonial flagellate, *Phaeocystis*, may deflect the spawning shoals of herring from their usual grounds. The other correlation showed that, on the average, more herring were caught when the copepod, *Calanus*, was abundant than when it was scarce. The plankton indicator has been used by a number of fishermen with success; according to the appearance of the sample they either shoot their nets, if the signs are promising, or move on to another place (taking samples en route) if they do not appear satisfactory.

In addition to studying the structure of the different types of plankton, most valuable work has been done in marine stations on the conditions which are necessary for their life. There the nature of the annual cycle in the sea was worked out and the first attempts were made by J. E. Allen to provide a suitable mixture of nutrient salts which would allow full and free growth of the plants in the laboratory. While all require the phosphates and nitrates which are familiar in plant growth on land (artificial manures), the specific additional needs for full growth are difficult to discover. So far, only a small proportion of even the best known have been cultured in this way, but success with them has laid the basis for an attempt at larger scale work. From the small flasks of the laboratory, one step was to "manure" large tanks of natural sea water in which oysters could be placed to lay their eggs, so that their planktonic larvae should have an abundance of plant food as they hatched; after this nursery period they were transferred to commercial oyster beds for later growth. Another experimental step was to construct a plankton well which could be filled with sea water, manured and inoculated with plankton; it was then used for observing aspects of planktonic life which can not be studied in the sea and may never proceed satisfactorily on a small scale. A development of this was to isolate a small area of the sea (a small sea loch), to manure it and compare processes in this part with those near by where only natural nutrients were found. The benefits of artificial manuring were seen in the increased quantities of planktonic plants and animals. More important was the large-scale proof of the effect this had upon the bottom animals in the experimental stretch of water; they also increased and, in turn, supplied enough food to young fish placed in the water to enable them to grow at twice their normal rate.

In his early attempts to introduce rigorous methods into plankton research, the pioneer Victor Hensen hoped to be able to estimate, from actual counts of plants and animals, the productivity of different parts of the sea. If he was not successful it was mainly because much more knowledge was needed before even approximately useful estimates could be made. The plants must

be the basis of any estimates of production, but their total numbers at any moment bear little relation to what has been, or what will be, produced during the year; many have yet to appear and others have already sunk to the bottom or been converted into animal tissue. Better estimates are made from knowledge of the decreases of nutrient salts in a body of water and the amount of phytoplankton they may produce. In the English channel, for example, something like five tons of wet plant material is produced each year, on the average, for each acre of surface; this may be compared with the similar average yield of potatoes on land and the higher weights of some other crops. Only a fraction of this weight is now available to man in the form of edible fish, etc. (although some forms of plankton, particularly *Calanus*, are quite eatable both in the raw and cooked state); but it is possible that future methods may, by a rational conservation and exploitation of the seas' resources, greatly increase this fraction.

PLANTAGENET, a surname conveniently, but unhistorically, applied to the royal line descended from the union of Geoffrey, count of Anjou, with the empress Maud, who are now styled by historians the Angevin house. It was, historically, only a personal nickname of Geoffrey, as was "Curtmantel" of his son (Henry II), and was derived from his wearing in his cap a sprig of the broom (*genet*) plant. When the fashion of personal nicknames passed away, the members of the royal house were usually named from their birthplace, as Thomas "of Brotherton," Thomas "of Woodstock," and so forth. But Edward I and his younger brother, the founder of the house of Lancaster, had still nicknames respectively, as "Longshanks" and "Crouchback." In the later days of the dynasty the surname of Beaufort was adopted by the legitimated issue of John of Gaunt by Katherine Swynford, but that of Plantagenet was bestowed on Arthur, natural son of Edward IV, who was created Viscount L'Isle. It appears, however, to have been adopted as a surname by Richard, duke of York (father of Edward IV), about 12 years before his death.

At the death of Geoffrey's grandson, Richard I, his younger brother John succeeded. John's younger son, Richard, king of the Romans, left a son Edmund, earl of Cornwall, with whom his line ended; his elder son, Henry III, left two sons, of whom the younger was created earl of Lancaster and was grandfather of Henry, earl of Lancaster, whose heiress married John of Gaunt (i.e., Ghent). (See LANCASTER, HOUSE OF.) John of Gaunt's next brother, Edmund of Langley, founded the Yorkist line. (See YORK [HOUSE OF].) Although no other dynasty has reigned so long over England since the Norman conquest, the whole legitimate male issue of Count Geoffrey Plantagenet became extinct in 1499. See EDWARD VI (genealogical table).

PLANTAGINACEAE, a family of dicotyledonous herbs, the best-known members of which are the plantains (*Plantago*), cosmopolitan weeds, of which 5 species occur in Great Britain and upward of 30 in the United States. (See PLANTAIN.) The family contains 3 genera and about 260 species. The seeds of *Plantago psyllium* (Mediterranean) are used in silk and cotton manufacture. The flowers, usually hermaphrodite and inconspicuous, are wind pollinated. For a monographic treatment see R. Pilger, "Plantaginaceae," *Pflanzenreich* 102 (iv, 269): 1-466, f. 1-44 (1937).

PLANTAIN, a name given to certain plants with broad leaves. This is the case with certain species of *Plantago*, *Alisma* and *Musa*, to all of which the term is popularly applied. The species of *Plantago* (family Plantaginaceae) are mostly weeds with a dense tuft of radical leaves and scapes bearing terminal spikes of small flowers; the long spikes of *P. major*, when in seed, are used for feeding cage birds; *P. lanceolata*, so-called from its narrow lanceolate three- to six-ribbed leaves, is popularly known as ribwort.

P. psyllium and *P. indica* produce leaves in whorls on branched stems; their mucilaginous seeds are used as demulcents under the name of *Psyllium*, *Alisma plantago-aquatica* (family Alismataceae) is the water plantain. The tropical fruit known as plantain belongs to the genus *Musa*. (See BANANA.)

PLANTAIN EATER: see TOURACOU.

PLANTAIN LILY: see HOSTA.

PLANTATION, literally the placing of plants in the ground, hence a place planted or a collection of growing things, particularly used of ground planted with young trees. The term was early applied, in a figurative sense, to the settlement of people, and particularly to the colonization of North America in the early part of the 17th century and to the settlement of Scottish and English in the forfeited lands in Ireland.

The practice of sending convicted criminals to serve on the plantations in the colonies became common in the 17th century (see DEPORTATION).

For the history of plantation in southern United States, see SOUTH, THE, and for "plantation songs" see NEGRO, THE AMERICAN.

PLANT BREEDING. Not until the middle of the 18th century was the sexual nature of plants incontrovertibly demonstrated, and the term "plant breeding" did not become widely used until after 1900. Thereafter the intentional breeding of superior plants quickly became a world-wide activity; by the middle of the 20th century the breeding of field and horticultural crops was so standardized that it was largely in the hands of experts, much of it centred in a few large agronomic and horticultural institutions operated mostly at government expense.

For a variety of reasons the breeding of new and superior ornamental plants, though carried on in part by scientists and by tradesmen, was largely in the hands of gifted amateurs. As the result of their efforts, thousands of new varieties of dahlia, gladiolus, African violet, peony, narcissus, iris and rose came into being.

The breeding and purveying of these new varieties to the public spawned hundreds of small business enterprises. In the U.S. alone the business of producing and marketing new varieties of African violets was, by the mid-1950s, grossing more money per year than all the marketing of fruit trees, vines and bushes (both temperate and subtropical) in the same area.

Mode of Reproduction.—Any successful plant breeding program must be based upon a sound understanding of the exact mode of reproduction of that plant. Plants may reproduce in two ways: (1) vegetatively (that is, asexually) through the increase of a small portion (bulbs, tubers, etc.) of the original plant; and (2) sexually through the flower and seed. Even for those plants in which vegetative reproduction is not highly developed under natural conditions, the artificial rooting of cuttings and the grafting of roots and of stems, make it possible to disseminate pieces of a superior individual by vegetative means. Asexual propagation through seeds is of fairly frequent occurrence in the higher plants, and careful research work is required to establish the exact degree to which it may be a factor in any breeding problem. Either an unfertilized egg cell may develop into a mature but very weak plant (and yet of potential economic importance to the hybrid maize industry, for example, since such a plant offers a rapid means of isolating useful, true-breeding strains), or in any one of several different ways the embryo in the seed may be formed directly from the tissues of the mother plant.

Frequently the two processes go forward side by side so that some seeds are true sexual offspring and others from the same seed head are vegetatively derived from the mother plant. The more thoroughly these matters have been investigated for any particular crop, the more completely it is possible to set up a successful breeding program. Vegetative reproduction is of great practical importance in permitting the rapid increase of a single desirable individual.

Different kinds of plants not only vary in the extent to which they may be propagated sexually, but also in the degree to which they are naturally inbred or outbred. Among the higher plants both extremes are found. There are crops such as wheat which are naturally very inbred, being almost completely self-pollinated.

Others such as maize are mostly cross-pollinated under field conditions, though self-pollination is possible by artificial means. Still others (many plums for instance) are naturally self-sterile and cannot be self-pollinated though any particular flower may function effectively as either a male or a female in crosses with other plants.

Self-Fertilizing Species.—Naturally self-fertilized species have largely been improved by pedigree or pure-line selection. Most of the older varieties of wheat, oats, barley, cotton, beans and tomatoes have so arisen. However, as the ceiling of remaining variation is reached by selection, hybridization of pure lines is resorted to for further improvement. The pure-line method of breeding is based on the principle that the progeny of any individual plant selection in naturally self-pollinated species breeds true. The problem is then one of isolating the superior pure lines and increasing stocks of these.

Proper statistical treatment is often essential in detecting the most efficient strains. The second quarter of the 20th century showed a remarkable increase (virtually world-wide) in the expert use of field plot techniques for estimating the extent to which yield differences are due to inherent superiority rather than favourable soil or climate.

Cross-Fertilizing Species.—Naturally cross-fertilized species are more difficult to handle, because any inbreeding necessary to fix desirable characters often leads to a decline in vigour. One may accordingly use continuous mass selection broadly, avoiding inbreeding. One may, on the other hand, use a combination of inbreeding and controlled hybridization to utilize the phenomenon of hybrid vigour as was done so spectacularly in hybrid maize improvement.

Hybrid Maize.—The hybrid corn industry in the U.S. traces back to the scientific research of G. H. Shull and E. M. East who reported their results of inbreeding followed by hybridization in 1907-10. Not until the 1920s were these theoretical results incorporated into practical breeding programs. Phenomenal increases in uniformity, in yield, and in resistance to lodging and disease then became possible. As late as 1933 only a fraction of 1% of the Iowa corn acreage was devoted to hybrid corn, but in less than 10 years the percentage was 99.

The bases for hybrid corn are self-pollinated or highly inbred lines. These inbreds are crossed, usually detasseling the mother rows to make either single crosses (line A $\times$ line B), or by utilizing these single crosses to produce double crosses (the cross of line A $\times$ line B crossed with the hybrid of line C $\times$ line D). Most commercial field corn is produced from double crosses. Seed from the commercial crop is not saved by the grower for seed stock the next year but new seed is purchased each year from expert corn breeders. This has led to the development of a multi-million dollar hybrid seed corn industry which produces seed for most of the commercially important maize-growing areas in the U.S. and exports a fair amount to other countries.

Use of Male Steriles.—This inbred-crossbred breeding method is technically facile in maize because the male ("tassel") and female ("ear") inflorescences are in different parts of the plant, making artificial self-pollination or controlled cross-pollination economically feasible even on a field scale. Few other crop plants are so readily manipulated, but by the use of male-sterile strains the mass production of cross-bred seed is made possible. It requires such a precise understanding of the genetics of the crop in question that male-sterile plants can be created at will. They are then grown in isolated plots adjacent to male-fertile lines of the variety which is to serve as the male parent and the desired matings are produced naturally by insect or wind pollination.

Hybrid tomato seeds quickly became a commercial success by this method and the use of male steriles for the more economical production of hybrid seed was soon extended to other crop plants, including even maize (where it helped reduce the expense of artificial detasseling).

Breeding Bacteria and Fungi.—Breeding of bacteria and fungi for increased efficiency in fermentation processes quickly passed from the experimental into the industrial field. Beginning in 1935 with work in Denmark, better strains of yeast were pro-

duced by hybridizing different species and varieties. The rapid development of antibiotics led to large scale selection and breeding programs with many strains of micro-organisms.

Polyploidy.—It was a full quarter century after the improvement of small grains had been reduced almost to a rule-of-thumb before the significance of chromosome numbers in plant breeding was well understood. Gradually it was realized that a considerable proportion of the higher plants have their germ plasmas arranged in several sets of chromosomes. The simplest condition is like that which prevails among the higher animals. There are two sets of chromosomes and the species (or variety) is said to be diploid. However, there are in the higher plants many species and varieties with four (tetraploid) or six (hexaploid) or even more sets. Any organisms with more than two sets is said to be polyploid. Generally speaking, polyploids with even numbers of sets of chromosomes are more or less fertile, those with odd numbers being generally sterile, sometimes completely so. For instance, if a cross is made between a fertile tetraploid and a fertile diploid, the hybrid normally inherits two full sets from its tetraploid parent and one set from its diploid parent and is in consequence a triploid, which may be quite sterile for this reason alone. Breeding programs with such organisms must, to be successful, take polyploidy into account. They may work with diploids and tetraploids to produce further triploids. They may, by expert manipulation with such external agents as colchicine, at length succeed in doubling the chromosome numbers of the sterile triploids, producing fertile hexaploids from them.

As an understanding of the main facts of polyploidy gradually spread to more and more amateurs and tradesmen, the improvements of such partially polyploid ornamental crops as irises, orchids, and narcissuses lost much of their mystery. In all of these crops polyploids are often intrinsically more valuable than diploids since an increase in flower size and keeping quality frequently goes along with polyploidy. All of these crops had tended to have the smaller diploid varieties of a century ago, replaced by the larger flowering tetraploids and triploids when they accidentally arose.

Until the significance of chromosome numbers to breeding problems was generally realized, plant breeders did not know how to interpret the differences in breeding behaviour between closely related triploids and tetraploids. The development of rapid methods for determining chromosome numbers and the consequent clarification of various breeding problems related to polyploidy has catalyzed both amateur and professional plant breeding with such crops.

Plant Breeding Institutes.—Some well-known centres for plant breeding at mid-20th century were: *Australia*—department of agriculture, Sydney; *Brazil*—Instituto Agrônômico do Estado de São Paulo, Campinas; *Canada*—Dominion Experimental farm, Ottawa; *England*—University of Cambridge, school of agriculture, Cambridge, and Welsh Plant Breeding station, Aberystwyth; *Germany*—Kaiser Wilhelm Institut für Züchtungsforschung, München; *India*—Indian Agricultural Research institute, Pusa, New Delhi; *Sweden*—Sveriges Utsädesförening, Svålof; *United States*—U.S. department of agriculture, Washington, D.C.; regional laboratories at State College, Pa., and Charleston, S.C., and state experiment stations with well equipped laboratories and experimental plots (California, Connecticut, Illinois, Indiana, Iowa, Minnesota, Missouri, New York, Ohio, Wisconsin).

PLANT CELL (TISSUE) CULTURE. The cultivation of specific tissues or of specific organs apart from the complete organism on artificial media inside sterilized glass containers is commonly spoken of as tissue culture. The cultivation of plant cells by this means is treated in this article. (See also ANIMAL CELL (TISSUE) CULTURE.) Isolated small groups of cells, such as root tips, cambium and growing points, are separated from the rest of the plant and grown on suitable culture media. The procedure is comparable to that employed with bacteria and fungi. It makes available for physiological study of specific parts of

higher plants the techniques used so successfully with microorganisms. Without interference from influences of other parts of the plant, for example, it is possible to determine what metabolic substances and what amounts of each one may encourage growth, what ones may inhibit growth, and what materials are produced by the attendant physiological processes.

History.—The need for growing isolated portions of higher plants *in vitro* (i.e., in glass) was long recognized. A critical step forward was made in 1922 simultaneously by workers in Germany and in the U.S. with the cultivation for some weeks of root tips from peas, cotton and corn in artificial media. These media contained yeast extract or meat extract, sugar and mineral salts. The cultivation of tomato root tips for as long a time as desired in a comparable medium was achieved in 1934. The callus or "tumour" type of culture was achieved in 1939 by several different investigators working simultaneously and independently in France and in the U.S. Among the early successful cultures were those secured from carrot root sections, from natural galls occurring on tobacco hybrids, and from tissue resulting from inoculations with the crown gall bacterium *Agrobacterium tumefaciens* (Smith and Town.) Conn. Furthermore, excellent media were perfected which contained only nutrients with known chemical formulae. This positive information about every nutrient present was a great advantage for physiological studies. For example, with blood serum or coconut milk in the medium, it was difficult to tell which portions of these complex materials encouraged growth. Furthermore, if analyses of the medium were made after growth, it was difficult to differentiate between the compounds in the original medium and those produced during the growth process.

Many kinds of tissue have been cultivated from a number of different plants. Over 200 kinds of cultures have been made mostly from diseased or normal growth of the dicotyledons. However, some cultures also have been made from monocotyledons, ferns and other plants. Thus the way was opened for applying to portions of higher plants the standard bacteriological, physiological and biochemical techniques so long and fruitfully employed with bacteria and fungi.

Nutritive Media.—The nutritive media most commonly employed contained nitrate as a source of nitrogen, some ordinary sugar as a source of carbon, and well-balanced common mineral salts. The tissue from diseased growth commonly manufactured enough hormones and vitamins so that none were added. However, some cultures from normal tissue needed supplements such as coconut milk, yeast extract, or traces of indole-3-acetic acid or naphthalene acetic acid. For root tips, liquid media were commonly used. For other cultures, 0.6% agar was ordinarily added to support the tissue on the surface. The basic media were modified so as to secure much fundamental information about the nutritional requirements of the various tissues and also about the critical balance of concentrations that favoured or inhibited growth and that influenced differentiation.

Tissues Cultivated.—A series of different kinds of tissue were grown in culture by the following aseptic techniques: To secure root tips, a surface sterilized seed was germinated and about 1 cm. of a root was removed aseptically and placed in a shallow sterile liquid medium in a flask or bottle. To secure growth from plant embryos, a fairly mature and actively growing embryo was removed aseptically from the ovary. Ordinarily they required a well-enriched medium. Such technique permitted the growth of plants from certain cross pollinations which otherwise never would have developed. "Nurse" technique, discussed below, has offered possibilities with much younger embryos. For callus or "tumour" cultures, galls with as little contamination as possible were cut into a large number of pieces about 2 mm. across. Many of them were contaminated with bacteria or fungi, but perhaps one-fifth were aseptic. Among these, several grew satisfactorily in tissue culture. For callus from normal tissue, similar isolations were made aseptically of sizable pieces from actively growing parts such as the growing tip or the cambium. Usually normal tissues required some such supplement as a trace of auxin. In certain cases, such normal tissue became "habituated" during culture so that it grew without added auxin.

The tissues in culture varied enormously in their rate of growth—from extremely slow to rapid, some doubling their weight in five days. Those which grew rapidly were transferred after four to eight weeks. The amount of growth was measured either by visual estimate or by removing the tissue from the culture medium and by weighing it.

Contaminations have been a continual problem with tissue cultures, as with any other pure culture procedures. Certain fungi or bacteria sometimes grew inside the tissue mass without being apparent from the surface. Consequently routine maceration and incubation of a tissue sample in a rich medium was a necessary routine to reveal any contamination if it were present.

Application.—The applications of this relatively new but extremely useful technique have covered much of biology. This subject has been discussed in the article *ANIMAL CELL (TISSUE) CULTURE* and is not repeated here because of the fundamental similarity in growth and metabolism shown by cells in plants and in animals. The work with plant tissues has three important experimental advantages over that with animal tissues: (1) Culture media for animal tissues commonly contain complex substances like serum and embryo extract. By contrast, most plant tissues grow on simple synthetic media, with the experimental advantages explained earlier. (2) Animal tissues commonly require a change of nutrient every few days, a time-consuming process associated with elaborate precautions against contaminations. Most plant tissues grow satisfactorily for a month or more on the original medium. (3) Many animal cells send pseudopods or dendrites into the substratum so that cells and media are inseparable. The kind and amount of growth are relatively difficult to measure. The plant cells have no such processes. After incubation, the cultures are removed from the medium and the amount of growth is measured precisely by weighing the tissue and by subtracting the weight of the original tissue piece. Thanks to such techniques, a number of important basic studies have been completed.

The nutrients necessary for stimulating growth have been studied intensely with various tissues, and the common sources of carbon, nitrogen, mineral salts, vitamins and hormones have been established. Rather strikingly the amount of the nutrient often has appeared to be as important as its chemical formula.

The inhibition of growth correspondingly has been demonstrated for certain common metabolic substances. Among these were some of the simplest of the organic acids, their homologous alcohols and a number of amino acids. The size of the tissue mass apparently was critical in determining whether or not the tissue could grow in the presence of certain mildly inhibiting metabolites. An inhibition by certain antibiotics, such as terramycin and aureomycin, was demonstrated.

Some factors influencing the differentiation of tissues have been clarified in a striking manner. Tobacco pith tissue formed roots or shoots in culture depending upon the presence of a suitable balance in the amounts of auxin, adenine (an amine purine), kinetin (6-furfurylamino-purine) or related substances. Numerous chemicals similar to kinetin were active in stimulating cell division and growth. Various growth stimulating factors were found in coconut milk, in horse chestnut milk and in actively growing tissues.

Large mass cultures of plant tissue are theoretically possible. A medium was developed which was so effective that a liquid culture became solid in several weeks from the extensive cellular growth. Tissues from various alkaloid and food-producing plants were cultured. The possibilities of plant tissue cultures for food or special chemicals remain to be explored.

The use of tissue cultures for studying various plant diseases opened several important fields. For example, certain rust and mildew fungi, which do not grow on ordinary media, were grown on tissues in culture. Likewise, nematodes (roundworms) pathogenic on plants were thus cultivated. Certain viruses have been carried for years on tissues in culture and have been used for fundamental studies on virus multiplication and inhibition. Tissues from plant galls incited by insects have also been successfully established. The complete physical and chemical control of such tissues in vitro provides many experimental advantages for basic research; e.g., on pathogenicity, susceptibility and resistance.

An important potato-variety, in which all plants were infected with virus, was freed from the virus by tissue culture. The cells at the growing tip of a rapidly growing shoot were found to grow away from the virus. These cells were cut out aseptically and grown in tissue culture, and from these cells potato plants without the virus were again developed.

Cultures grown from individual cells of higher plants isolated from the established cultures were made possible by the development of a "nurse" technique. In numerous trials, an individual cell was placed aseptically on filter paper and that on living plant tissue in culture, which nourished the single cell through the paper. These plant cells have no dendrites or pseudopods that might grow through the paper. The clones of tissue thus derived showed that the original tissue mass was not homogeneous, but contained cells with various different char-

acteristics. With this "nurse" technique or a suitable modification, cultures are possible of numerous tissues both from plants and animals which otherwise would not grow.

These and other phases of the tissue culture technique made practical numerous investigations of a fundamental nature, including those dealing with diseased growth, many of which appeared to be near the heart of the cancer problem.

(At. J. R.; A. C. Hr.)

PLANTIN, CHRISTOPHE (1514–1589), French printer, was born in a village near Tours (probably Saint Avertin). He learned bookbinding and bookselling at Caen and, having married in that town, settled in 1549 as bookbinder in Antwerp, where he was soon known as the first in his profession. A bad wound in the arm seems to have been the cause that first led him (about 1555) to apply himself to typography. The first known book printed in his office was *La Institutione di una fanciulla nata nobilmente*, by J. M. Bruto, with a French translation, and this was soon followed by many other works in French and Latin, which in point of execution rivalled the best printing of his time, while the masters in the art of engraving then flourishing in the Netherlands illustrated many of his editions. In 1562, Plantin himself being absent in Paris, his workmen printed an heretical pamphlet, which caused his movables to be seized and sold. It seems, however, that he recovered a great deal of the money, and in 1563 he associated himself with some friends to carry on his business. Among them were two grandnephews of Daniel Bomberg, who furnished him with the latter's fine Hebrew types. Christophe produced editions of the Bible in Hebrew, Latin and Dutch, a *Corpus juris* and Latin and Greek classics.

A much greater enterprise was planned by him in those years—the publication of a *Biblia polyglotta*, which should fix the original text of Old and New Testaments on a scientific basis. In spite of clerical opposition he was supported by Philip II, king of Spain, who sent him the learned Benedictus Arias Montanus to superintend the work. It was finished in five years (1569–73, 8 vol. folio).

Plantin earned little profit, but received the privilege of printing all liturgical books for the states of King Philip, and the office of "prototypographus regius." Though outwardly a faithful son of the church, he was till his death the partisan of a mystical sect of heretics.

Besides the polyglot Bible, Plantin published in those years editions of St. Augustine and St. Jerome, the botanical works of Dodonaeus, Clusius and Lobelius, the description of the Netherlands by Guicciardini, etc. In 1575 his printing office reckoned more than 20 presses and 73 workmen, besides a similar number that worked for the office at home. But in Nov. 1576 the town was plundered and in part burned by the Spaniards, and Plantin had to pay an exorbitant ransom. He established a branch of his office in Paris; and when in 1583 the states of Holland sought a typographer for the newly erected university at Leyden, he left his much reduced business in Antwerp to his sons-in-law John Moerentorf (Moretus) and Francis van Ravelingen (Raphelengius), and settled there. When in 1585 Antwerp was taken by the prince of Parma and affairs there became more settled, he left the office in Leyden to Raphelengius and returned to Antwerp, where he worked until his death on July 1, 1589. His son-in-law, John Moretus, and his descendants continued to print many works of note "in officina Plantiniana," but from the second half of the 17th century the house began to decline. It continued, however, in the possession of the Moretus family, which religiously left everything in the office untouched, and when in 1876 the town of Antwerp acquired the old buildings with all their contents, for 1,200,000 fr., the authorities created one of the most remarkable museums of its kind in existence, the Musée Plantin, opened Aug. 19, 1877.

(P. A. T.)

PLANTING MACHINERY. The two principal methods of sowing seed in ancient times were broadcasting and dibbling (making holes in the ground for the seed). The former method, employed, for example, with cereal crops, resulted in the hap-

hazard deposit of seeds at various depths and distances; the latter method, employed for planting larger seeds, was laborious. However, after the middle of the 19th century machines were devised to do many kinds of planting. The requirements of the various crops differ, and the character of the soil and climate lead necessarily to different practices in planting.

In general, planting machinery may be divided into two groups, one consisting of equipment designed largely for planting broad-

the box of a wagon and is chain driven from a sprocket fastened to the wagon wheel, consists of a hopper into which the seed is shovelled from the wagon box, two feed runs of the fluted force-feed type, and spouts leading to two centrifugal devices which distribute the seed. Small grains such as oats and wheat as well as flax, clover, timothy and other small seeds may be broadcast from such a seeder. Broadcasting does not, however, ensure the seed being covered to a uniform depth, but the machine called a drill is more efficient in this respect. The drill not only places the seed in rows at a suitable depth but also covers it.

Drills.—Drills may be classified according to the type of feed: force-feed (either external fluted roll or internal double-run) and cup-feed; or according to the type of furrow opener used, as hoe, shoe, single disk and double disk. The drill consists essentially of a frame, mounted on an axle (sometimes two short axles are used with wheels mounted on the outer ends), supported by a wheel on each end, furrow openers with covering chains or press wheels, seed box, seed measuring device for each furrow opener, and tubes to conduct the seed to the furrow openers. Occasionally entrances to certain of the measuring units are enclosed to permit drilling small acreages of cultivated row crops such as sugar beets, mangels, etc. In the force-feed drill the seed box has one compartment, and this has a bottom composed of a number of small hoppers or feed runs. The feed devices revolve in these and cause a measured amount of seed to be deposited in the tubes connected to the furrow openers. The lower ends of the seed tubes pass into boots connected with the furrow openers or runners.

In the *external fluted feed type* (fig. 1) a fluted roll revolves in the bottom of each small hopper. The quantity of seed sown per acre is controlled by exposing more or less of the feed roll to the seed inside of the feed cup, although in some machines the feed may be further controlled by adjusting the size of the opening through which the seed flows. In the *internal double-run type* of drill the rate of sowing is regulated by altering the speed of the drive shaft by gearing devised for the purpose and by a small gate inside the feed cup. The double-run feed wheel or disk (fig. 2) is flanged on both sides with corrugations around the insides of the rim—coarse on one side for large seed and fine on the other side for small seed.

The *cup-feed drill*, used mainly in the flat land of southeast England, has a seed box divided into compartments, and must be kept level to ensure a uniform supply of seed to each distributing unit. In a separate chamber behind the seed box there is a horizontal geared shaft carrying a number of flat disks with cups mounted on each side at the periphery for lifting the seed from small hoppers or feed runs into funnels connecting with the furrow openers. The seed passes from the seed box to the feed runs through apertures which may be fitted with slides for regulating the supply of grain at this point. Cups may be made with two seed faces so that by reversing the shaft different kinds of seed can be sown. The shaft is driven by a pinion from one of the drive wheels, and the rate of sowing can be altered by using pinions of different sizes.

Furrow openers are of different kinds. The *hoe furrow opener* (fig. 3) consists of a single- or double-pointed shovel fastened to the lower part of the boot which is usually fitted with a replace-

COURTESY OF JOHN DEERE

Fig. 1.—External fluted feed type drill. The picture shows what happens from the time the seed leaves the seed box until deposited in the seed furrows and covered by the covering chains. Part of the seed cup and spout has been cut away to show how the seed falls into the big-capacity seed cup, is picked up by the flutes of the feed roll, carried over the adjustable gate, and released into the grain spout. Closed rear-delivery disk boots deposit the seed on the bottom of the trench before any soil can drop back.

cast or in closely spaced rows, and the other consisting of equipment for planting intertilled rows, frequently with hills spaced uniformly in the row.

The *broadcaster, or seeder*, in its simplest form consists of a *knapsack* for carrying the seed with a hand-operated centrifugal device for scattering it, or a long seed box carried on a *wheelbarrow* frame with an agitator operated from the ground wheel to throw out the seed. These simple machines are used mainly for grass and clover seeds. For broadcasting cereals it is more usual to use a cultivator or disk harrow fitted with a seed box and broadcasting device. However, in the *endgate seeder* the centrifugal idea is also used. This seeder, which attaches to the rear of

able break pin or compression spring for its protection when encountering an obstruction such as a heavy stone or large root. The *shoe opener* (fig. 4) is made from two flat pieces of steel on edge welded together in a wedge and curved upward at the front. The boot is attached on the upper side at the rear and open end of the wedge. The *single-disk furrow opener* (fig. 5) is saucer-shaped, similar to a disk harrow disk. It is for cutting through trash and is of two types, the open boot where the disk serves as one side of the seed tube and the closed boot where a separate

COURTESY OF JOHN DEERE
Fig. 3.—Hoe-type furrow opener

tube extends to the bottom of the furrow. The latter is better for use in sticky soils. Half of the openers of this type are assembled with concave side facing one way and the other facing the other way. The *double-disk opener* (fig. 6) consists of two disks, usually flat, facing each other at a slight angle to form a wedge where they penetrate the soil. By this arrangement a small ridge is left in the furrow, causing the seeds, as they are deposited, to make two distinct rows approximately 1 in. apart. Pressure is usually applied to furrow openers by weights or springs to get the required penetration in all sorts of soils. Grass-seeder attachments are available for use with most drills, as are also fertilizer attachments, with hoppers the full length of the drill seed box and feeding mechanism driven from the main axle. The delivering tubes from the grass seeder usually lead into the main drill tubes, and the fertilizer tubes may either lead into the drill tubes or be entirely separate. Combination grain and fertilizer drills, also considerably used, have a large hopper divided longitudinally into two compartments—one for seed, the other for fertilizer. The seeding mechanism is the same as in the regular grain drills, but the fertilizer compartment is usually provided with revolving horizontal star-type feed wheels and means of regulating the rate of application. Tubes similar to those used for seed conduct the fertilizer to the furrow openers. Seeding attachments resembling a grain drill are sometimes mounted on a one-way disk plow (disk tiller) or on a corrugated roller or soil pulverizer, on the latter mainly for sowing grass seed.

For planting beets or beans, drills fitted with the same type or internal double-run feed, as is used in wheat drills, are available, both plain and fertilizer, which plant in rows 18, 20, 24, 26 or 28 in. apart and have provision for alternate narrower and wider spacings. For planting sheared sugar beet seeds (seed balls which

have been ground down to one germ as an aid to thinning the beet plants, which because of the nature of the seed normally come up in clumps), drills with special fluted feeds or drills equipped with holed plates similar to corn-planter plates are used.

Corn (Maize) Planters.—The predominating size of corn planter in the United States is the two-row, horse- or tractor-drawn, or tractor-mounted, although a considerable number of four-row machines are in use. This planter, in many cases, is adaptable to the planting of cotton, soybeans or any other crop grown in intertilled rows and having seed of comparable size. The two-row drawn type (fig. 7) consists essentially of two main wheels—open-centre type (space between the bevelled outer rims), closed type (solid concave surface) and fitted on the ends of an axle, or double wheels (two narrow-tired wheels close together at bottom and wide apart at top), which support a frame carrying the planting mechanism and sometimes a fertilizer attachment driven by one of the main wheels. (The horse-drawn type is equipped with a driver's seat.)

A vertical cylinder-shaped seed box is provided for each row. In the bottom of this box is a revolving seed plate with seed cells. Plates are available with holes of various sizes for the size of seed to be used. If the corn is to be drilled, the seeds fall at regular intervals directly into the boot (fig. 8) of each furrow opener and thence into the ground as the plate revolves and the cells register with the opening underneath. The seeding rate or the spacing in the row depends upon the rotation rate of the seed plate and the number of cells in the plate. (Corn planters are available for drilling only, but checkrow planters can be used as drills by locking open the valves in the boots.) If the corn is to be checkrowed

(planted in checkerboard fashion) a planter with a check head is used, and this requires a check or trip wire with uniform-spaced buttons. (Spaced same as centre-to-centre spacing of wheels and furrow openers which are adjustable from around 30 in. to 48 in. apart.)

With the trip wire laid across the field in the direction of planting, the planter in position and the wire placed in the check head, the operation is as follows: as the machine proceeds the drive wheels actuate a feed shaft, which causes the seed (2, 3 or 4 per hill, selected according to the nature of the soil) to be deposited in the upper valve. As the button trips this valve, the lower valve already charged with seeds discharges into the furrow opener and into the furrow, and the seeds from the upper valve drop into the lower one ready for the next hill. The main wheels positioned directly behind the furrow openers then cover the seed and com-

Fig. 7.—Two-row horse-drawn corn planter. Open-centre main wheels

pact the soil around it. The common types of furrow openers are the stub runner, the curved runner, and the single and the double disk. Row markers are provided to keep the rows equidistant. Fertilizer attachments may be mounted on most planters, and usually discharge the fertilizer in bands on each side of the seed.

Listers.—In dry regions corn is sown or listed with an attachment to a middle buster (similar to a right- and left-hand plow bottom mounted back to back) designed to open a narrow furrow, in a previously prepared seedbed, into which the seeds are dropped and then covered by cover disks and compacted by press wheels. By altering the plates in the corn planters and listers cotton seed can be planted and also many other coarse seeds such as peanuts, beans and kaffir corn. (Cotton, however, is seldom checkrow planted.) The lister planter occurs in the one-row walking; one-row, two-wheel riding; one-row, four-wheel riding; one-row, wide-tread trench guide (main wheels set far enough apart to allow the wheel on either side to run in the bottoms of the last row listed and planted); two-row horse or tractor; and three-row tractor types. Usually fertilizer attachments are used on cotton planters. When the planter is equipped with large double-disked furrow openers it is called a loose-ground lister planter. This machine is used to plant seed in beds of warm moist soil with ridges of loose, well aerated soil between to absorb the rainfall.

Potato Planters.—In the United States machine planting is common practice, and two types of machines are used—the automatic and the semiautomatic, or assisted-feed. With the *automatic type*, one man only is needed to plant. As the machine is pulled forward on its two wheels, two disk coulter openers produce a ridge on both sides of which fertilizer is deposited (if provided with such an attachment). Following this is a V-shaped opener shoe which splits the ridge, opening a furrow for the seed pieces and covering the bands of fertilizer simultaneously. The seed pieces are deposited at uniform distances in the furrow by the dropping mechanism. This consists of a spider or disk to which are attached picker arms revolving through the seed potato hopper. Each arm, fitted with a picking hand or sharp staplelike

points, picks a seed piece as it rises in the trough in the hopper bottom. As the arm descends on the other side the seed is automatically dropped into the furrow and is covered with soil by a pair of saucer-shaped disks. Frequently a press wheel attachment is used in place of the covering disks.

The *semiautomatic*, or assisted-feed, planter differs from the

Fig. 8.—Planter boot and runner with split-row fertilizer boot attached. Left, rear view of the split-row boot with the soil dug away to show how the fertilizer is deposited in the soil in two distinct strips, one on each side of the hill, to prevent the fertilizer from coming in contact with the seed

automatic mainly in the dropping mechanism. This consists of a device to elevate the seed pieces from the hopper into the pockets of a horizontal revolving feed ring. One seed piece should be in each of these pockets—if there are two, one must be removed, and if none, one must be supplied. The feed ring carries each piece to the planting tube through which it drops into the furrow already prepared. This is a two-man outfit since it requires an extra man to attend the feed ring. These two types of planters are available in one-, two-, three- and four-row sizes, with row spacings varying by 2 in. increments from 32 in. to 42 in. Spacing in the row may be varied from about 6 in. to 24 in. by varying the dropping mechanism. Another type of planter used to some extent is the *cup type*. This consists of a series of cups which are attached to a chain and which are filled with seed potatoes as they are passed vertically through the seed hopper. As the chain proceeds the seed pieces are carried to the top and dropped into a seed tube leading to the furrow opener and into the furrow.

Machine planting of white potatoes is practised to some extent in the north of England and in Scotland. In the potato-growing districts of the Fens, however, mechanical planters are seldom used because of the damage caused to the sprouts on the seed pieces, which are generally allowed to sprout before planting.

Transplanters.—Where large quantities of such plants as cabbages, tomatoes, strawberries, celery, tobacco and sweet potato slips are to be set out, transplanting machines are much used. Many such machines not only set the plants but water them and firm the soil over the roots. There are two principal types, the manual-setting and the mechanical transplanters, both of which may be equipped with fertilizer attachments designed to place accurately a prescribed amount of fertilizer at the optimum position with respect to the plant. Both types have two main wheels in the rear and generally one or two steering wheels in front. The machine must be strong, for it must support the weight of the driver, two plant setters for each row (two-row machines are frequently used), a 40-gal. to 55-gal. steel tank containing water, and possibly 150 lb. of fertilizer and plants. The driver usually sits in a seat on the tank unless the machine is tractor drawn, and the plant setters may sit in seats ahead of or behind the tank and facing forward or backward, depending upon the design of the machine.

The *manual-setting type* usually has a subframe carrying the planting mechanism, which consists of a furrow opener or shoe, a water valve in the heel of the furrow opener, and press wheels or plates. As the machine proceeds down the field and the water valve opens automatically for each plant, the setters alternate in setting the plants in the furrow, which is immediately closed and compacted by the press mechanism. The distance between plants in the row may be varied from about 8 in. to 60 in. and between rows 26 in. or more, in special cases as close together as 15 in. In the *mechanical transplanter* the plant setters place the plants in transplanting pockets which firmly hold them and revolve on a sprocket chain until they are automatically released in the furrow already opened. As the plant is released the water valve supplies water and the packing device closes the furrow and compacts it.

Seeding of large acreages of some crops is also done by *aeroplane*. In California (U.S.) it is a common practice to sow rice from the air on flooded fields or onto the ground, to be flooded later—a method that in either case eliminates weeding cost and does not interfere with harvesting as the fields are drained before the crop is ready to cut.

PLANTING OF TREES: see TREE.

PLANT PROPAGATION. Plant propagation embraces the starting of plants as independent units, either from seed or by division of other plants. Since in most species seed are the result of fusion of male and female gametes, raising plants from seed is termed sexual propagation, while the various types of propagation by division are known collectively as asexual. The

plant kingdom spreads over climatic regions so dissimilar in temperature, in rainfall and in the distribution of these factors, that ability of the various species to maintain themselves has resulted in wide variation in the nature and behaviour of seed. The typical seed contains an embryo, often a supply of elaborated food and some sort of protective coating. In nature many plants of the temperate zone ripen their seed at such periods that prompt germination would result in the cold of winter destroying the young seedlings; in these species a full growing season for the seedlings is insured by the inability of the seed to germinate until it has been subjected to low temperatures (around 40° F.), combined with moisture, for a period of weeks, varying with the species. When such plants are taken into cultivation the treatment given their seed, in imitation of nature, is called stratification. Seed may be planted in autumn or stored, mixed with moist sand, in piles or boxes, in the shade of a building or in a cold storage. Contrary to a rather common notion, freezing is not necessary to effect stratification. Examples of this simple type of stratification requirement are afforded by apple, pear, peach, birch and some oaks. A more complicated requirement is an alternation of a cold period, a warm period and another cold period. Some hawthorns have this peculiarity and for this reason their seed has been called "two-year seed."

Dormancy in seed is of several sorts. In some cases the embryo itself is dormant and will not grow until the stratification (after-ripening) processes have been operative. In many cases, however, dormancy is due to the impermeability of the seed coat (not the "shell") and the seed will grow at any time when this is removed. Removal of the seed coat is a tedious process, wholly beyond the limits of practicability, except as a viability test, with many kinds of seed, particularly when stratification is so easily effected. In many of the leguminous plants, *e.g.*, black locust, clover, the seed is singularly impervious to water, and stratification has little effect; in these cases scarification or treatment for a few minutes with concentrated sulphuric acid or wetting with scalding water is adequate. Many plants of the temperate zone have no seed stratification requirement and it is rare in tropical plants.

The duration of germinative ability in seed varies greatly with the species; elm, magnolia and soft maple seed, among the temperate zone plants, and seed of many tropical plants, are short lived, in some cases lasting only a few days. Without mentioning extreme cases, it may be said that some weed seed have germinated after having been stored for 25 years. Lettuce seed is usually short lived, but melon seed frequently germinates well after four years. Retention of viability in seed is sometimes affected greatly by the conditions of storage. In the tropics, for example, cinchona seed often deteriorates greatly in three or four months without special care, but storage in dry atmosphere (maintained by calcium chloride) has prolonged its life with very little deterioration for as long as 30 months.

Many kinds of seed are sown in the open ground and, barring extreme wetness or extreme aridity, germinate well enough for practical purposes. Other kinds, however, are so exacting that their requirements are best met in a propagating house, *i.e.*, one in which temperature and humidity may be controlled more readily than is possible in the ordinary greenhouse. Because of their high oxygen requirement, the medium in which they are sown generally should contain more sand than ordinary garden soil. This greater porosity makes these media more subject to rapid drying, and moisture must be watched carefully. Sphagnum moss, shredded through a screen (one-third or one-fourth inch mesh), makes a very satisfactory seeding medium, combining high porosity with high water-retaining capacity, requiring less frequent watering but tolerant of excessive watering from above; it should not be subirrigated. Since many soils harbour fungi which are destructive to sprouting seed and young seedlings, sterilization, by heat or by chemicals such as formalin or chloropicrin, of the soil used for germinating seed is common. Seeds are often coated with various disinfectants containing copper or mercury. Some kinds of seed may carry destructive disease spores with them into a seed bed; pre-sowing treatments with disinfectants are effective

against many of these seed-borne diseases. Seeds sown in sphagnum are singularly free from damping-off fungi, even without disinfectants; the value of this medium as protection against seed-borne diseases has not been determined.

With a few cultivated crops practical advantage is taken of heterosis, or hybrid vigour, *i.e.*, enhanced vigour and productivity of the first generation descendants from crosses between two strains previously kept pure by selfing ("inbreeding") for several generations. In maize the "hybrid corn" by 1945 constituted a major portion of the crop of the United States. Introduction of the same procedure in the onion and tomato crops and with squash has been made. Distinction should be made between "hybrid seed" of this sort and the seed of hybrids, which may be quite different.

With crops which produce seed freely and "come true" from seed closely enough for the purposes in view, growing from seed is usually the cheapest and most satisfactory method of propagation. Some species of plants are grown, however, which in the cultivated forms do not produce seed, *e.g.*, banana, pineapple, sugar cane. In a great number of cultivated species seedlings vary so much that the desired traits would be found in only a small proportion of seedlings. Among dioecious plants the natural distribution of sex, approximately 50-50, does not suit the purpose for which they are grown. Female trees of ginkgo and poplar are undesirable for street planting; in date or pistachio orchards or muscadine grape vineyards, one male plant will effectively pollinate several pistillate plants and since the males produce no fruit a surplus would be a needless expense. To meet these various requirements asexual propagation, *i.e.*, division and indefinite subdivision of the original plant having the desired traits, is utilized.

For generation after generation many people have held—and voiced—the opinion that asexual propagation is unnatural and the plants thus derived lack the hardiness or the sturdiness of plants grown from seed. The only justification for this generalization is the fact that virus diseases can be transmitted by asexual propagation and in most—not all—cases they are not transmitted through seed. Otherwise the notion is founded on narrow observation. A plant producing exceptionally good fruit or exceptionally fine blossoms is likely to be propagated regardless of its vigour or hardiness; since the laws of chance rarely combine all the virtues in one individual, a plant selected for pre-eminence in one quality is likely to be average or inferior in another. The weakness is in the selection and not in the method of propagation. An apple tree selected for cold resistance and propagated by grafting is more hardy than most seedlings. Asexual propagation is not unnatural; in some forms, *e.g.*, layering and grafting, it is rather common in nature.

In some respects, the simplest method of asexual propagation is the form known as division, in which the aggregate of roots is cut roughly through the crown and the fractional parts planted out as separate plants. In dividing the dahlia, care must be observed that the bud is intact on each root, but in some plants, *e.g.*, rhubarb, buds are numerous and random division is generally adequate. In bulbous plants new buds form at the base of the old and may be separated from them and grown on. This process is hastened in the hyacinth by scooping or slitting the base of the bulb and replanting it. In the amaryllids the bulb may be sliced radially and from each section one to several bulblets arise, provided, in most species, the section includes a portion of the "pad." In the lilies, the bulb may be divided concentrically into scales, which form new bulbs. In the potato, the tuber may be divided into as many segments as there are buds (eyes), each of which when planted will produce a new plant, but in practice larger segments, which give the new stem a better start, through the greater supply of reserves, are ordinarily used.

The great majority of plants can be made to emit roots on their stems. Many do this naturally, particularly in a moist environment. Black raspberries, dewberries and one form of forsythia, for example, regularly develop roots at the tips of the stems, where these touch the ground. This process, "tip-layering," is often accelerated by pegging the tips so they will not sway in

the wind, or by placing a small amount of soil over the stems, leaving the tip bud protruding. At the end of the growing season the rooted tips are cut loose from the parent plant and set in plantations or in nursery rows. Some of the shrubs may be layered by so bending whole shoots that they can be pegged or held by stones, in shallow trenches, which are filled with earth a little at a time as the new lateral shoots grow. This method works best with the more vigorous varieties. A method used frequently with gooseberries and with the less vigorous clonal apple stocks is known as "mound layering"; this involves cutting back close to the ground an established plant and erecting progressively a mound around the bases of the new shoots as they develop. Cardinal principles in handling layering by these methods are: (1) to cover with soil the bases of the new shoots before they have hardened but after they have lost their original softness; (2) to keep the soil around the plants moist, but not wet. Production of roots is increased, if necessary, by wire constriction, or by ringing, *i.e.*, removing a ring of bark, or by notching the stem, just below the point where the roots are desired. With some plants the same effect can be obtained with less labour by twisting the stem. Aerial or "Chinese" layering brings the rooting medium around the stem at a point above the soil, sometimes high in the air. For this purpose, moss, or soil, is often bound around the stem and kept moist continuously. The care entailed makes this method rather costly. Layering in general is rather expensive in space and time and is not particularly successful in many soils and climates and in case other methods of vegetative propagation are reasonably successful they are generally preferred. For some plants, however, it is the only practicable method.

Plants whose stems emit roots readily are generally propagated by cuttings, as the preferred vegetative method. Wherever practicable, cuttings taken in the dormant season, comprising 6 to 12 inches, according to species, of the previous season's growth, and planted in the open, are preferred, as most easily handled. These are called "hardwood" cuttings (fig. 1A). Most American and some European grapes, currants, most poplars and willows are grown by this method. "Greenwood" or "semihardwood" cuttings, using shoots, ordinarily two to six inches in length, which are still somewhat succulent, are utilized with many plants which do not root freely from mature stems. Since these must retain some foliage if they are to root, they must be protected more or less against loss of moisture to the atmosphere; hence they are usually placed in a cold frame, hotbed, greenhouse or in a rather tight glass case inside a greenhouse. The medium in which they are set must be porous and free of rot-producing organisms; these requirements are generally met by using washed sand as the rooting medium. Frequent moistening of the sand is necessary, combined with maintenance of high atmospheric humidity. Cuttings set for rooting in cold frames generally require covering with sash and shade for maintenance of humidity. Temperature requirements of greenwood cuttings vary widely according to species; conifers in general root better, though slowly, at lower temperatures, while roses root better at higher temperatures. Important factors in success with greenwood cuttings are in selection of time for taking cuttings, in the degree of maturity of the cutting at the point where it is severed and, in some measure, in the general condition of the mother plant. In some cases better rooting is obtained with cuttings taken from plants grown under glass than from those grown outside. With carnations and many other plants the guide to proper condition is the type of fracture made when the cutting is broken from the parent plant; if the stem crushes, it is too young; if the fracture is "stringy," it is too mature; when it makes a clean fracture without crushing, the chance of success is highest.

In recent years treatment of the bases of greenwood cuttings with hormones or growth-regulating substances has received considerable attention. The principal materials used have been indolebutyric acid, naphthalene acetic acid, indole acetic acid and some of the phenoxyacetic acid compounds. Treatment is given by thrusting the bases into talc dusts containing one or more of these compounds, or by immersion of the bases in solutions containing them. Though the use of these substances has not had revolution-

ary effects, in the sense of rendering easy the propagation of difficult plants, it has increased the amount of rooting and through speeding the process could in some cases reduce the loss from fungus diseases in cutting beds. In some instances these substances have proven toxic to the cuttings unless great care is taken to use them sufficiently diluted. Recent studies have shown the possibility of rooting greenwood cuttings with fluorescent lights as the sole illumination, thus permitting the use of opaque structures where light and humidity can be controlled more readily than in glass houses.

When greenwood cuttings have rooted adequately they are generally potted or planted out. This stage may require some care in protection against sudden exposure to strong sun and drying air currents for a few days until the plants are established in their new environment.

Root cuttings, *i.e.*, pieces of the roots, ordinarily about four inches long, are used in the propagation of a few plants, *e.g.*, blackberries and clonal strains of black locust. These cuttings should be taken in the dormant season, either in autumn, during winter or early spring. Root cuttings of blackberry grow well if laid horizontally in rather shallow trenches, but root cuttings of clonal apple stocks seem to grow better if placed vertically, with distal end down, proximal end just below the surface of the ground. Obtaining root cuttings of most plants in quantity is expensive and the practical use of the method is limited.

Leaf cuttings, employing leaves only, or portions of them, are used in the propagation of a few plants. Leaves of many plants can be induced to form roots, but only a few will develop shoots in the absence of a pre-existing axillary bud from the stem. Many begonias and sansevieria are frequently propagated by this method.

FIG. 1.

(A) Hardwood cutting, (B₁), budstock with bud in process of removal, (B₂) removed, undersurface, (B₃) side view, (C) stock prepared for insertion of bud, (D) stock with bud inserted

Juvenility has received insufficient attention in connection with propagation by cuttings. Indefinite prolongation of the juvenile condition in certain conifers—the “retinosporas”—through cuttings has been practised from as early as the 1870s. Cuttings of young seedling plants of some species root rather readily while cuttings from somewhat older plants of the same kind root meagrely. It is not clear, however, whether indefinite continuance of propagation thus started with juvenile plants is possible, or whether an adult plant can be made juvenile again.

When vegetative propagation is necessary and layers and cuttings are not easily made, recourse to grafting is common. By this process a bud or a twig of the plant whose propagation is desired is transferred to another plant already supplied with a root system or capable of forming one readily. Some plants are grafted readily, others with difficulty and some cannot be grafted at all; the reasons for these differences are not always clear, but in some cases the difficulty seems connected with slow formation of the callus necessary to establish connection between the rooted plant, the stock, and the plant portion transferred to it, the scion. In other cases the rapid and excessive development of tyloses and wound gums, plugging the vascular tissue, seems the principal source of failure; in some cases latex formation is a factor. These difficulties may arise when stock and scion are of the same species. Grafts between species are often successful, between genera occasionally so, between families practically universally failures. Within the genus, closeness of relationship is not an infallible guide as to probable success, but in the absence of recorded experience it is the best available. Compatibility or congeniality in grafting is of various degrees. Apple grafts on oak fail immediately; apple grafts on

pear may grow well for one year or even two but gradually weaken and die. The ornamental crab apples derived from native American species grow indefinitely on common apple seedlings originally of European origin, but not as vigorously as on seedlings of the American species, and they fail utterly on certain of the clonal apple stocks. Some lilacs exist for a number of years, but fail ultimately, on privet stocks. Adaptability of the stock to its environment is often as important practically as is compatibility. Certain grape stocks are fully compatible with the scions grafted on them, but cannot survive in soils containing considerable amounts of lime. The apricot is, other things being equal, the best stock for apricots, but in moist soils in cool regions apricot trees frequently flourish better on certain plum stocks than on apricot. The differences in adaptability are, on the whole, beneficial in that they permit some greater degree of adjustment to soil conditions than would otherwise be possible.

The influence of the stock on the scion, and particularly on its fruit, has been discussed for centuries. It has been contended, for example, that a stock which itself produces sour fruit will exert an effect on the scion grafted on it so that it would bear acid fruit. This doctrine implies a passage of elaborated substances across the graft union; the implication is too sweeping. Some alkaloids seem to move across the graft union, but other plant products—inulin, for example—are purely localized and do not traverse the union. Oxidases seem to be localized. The general impression of higher quality in pears grown on a dwarfing stock—the quince—has been supported by chemical studies showing somewhat higher sugar content in pears so grown. In the apple the fruit grown on dwarfing rootstocks is rather consistently lower in acid than fruit of the same varieties grown on seedling stocks. In many fruits, *e.g.*, grapes, ringing single branches produces as great chemical differences in the fruit as any conceivably due to stock influence. On the same stock fruits vary in quality with the soils and climates in which they grow. Differences in stature of plants grown on certain stocks are very pronounced. The so-called dwarfing stocks in rather common use for apple and pear produce small trees, which come into bearing early—if in good soil—and never attain great size. Because of this trait they are utilized in growing trees destined to elaborate training on walls and trellises.

Though discussion of graft hybrids belongs more appropriately to fields other than propagation, it is so frequently injected into discussions of influence of stock and scion that mention of them seems necessary here. Though the manner of their origin makes them rare under ordinary circumstances, Hans Winkler succeeded in producing considerable numbers by special treatment of grafted Solanaceous plants. A graft hybrid is produced when an adventitious bud arises at the graft union and the shoot developing from it is composed of tissues derived directly from stock and from scion. The tissue arrangements are diverse; the outer tissues may be from one component and the inner from the other, constituting the so-called periclinal chimaera; one section of the shoot, internally and externally, may be derived from stock and the rest from scion, constituting the sectorial chimaera which might, theoretically at least, produce oranges on one twig, lemons on another or even fruits which are partly one, partly the other. A third type is a mosaic of tissues derived from both components. In all these cases, however, the several tissues are unchanged from those of their respective parent plants, while the sexual hybrid is distinct from either parent, but uniform throughout. (See CHIMAERA.)

The establishment of union between stock and scion is effected through the formation of callus, a loose growth of cells, by both stock and scion. When these meet they fuse into a mass so continuous that precise location of the line of union even with the aid of a microscope is frequently impossible. There is no evidence of a fusion of individual cells. At the initial union the cells are usually isodiametric; in the secondary stage tissue differentiation begins. The whole process is no more than a wound healing. Just as in wound healing, it proceeds more rapidly if the wounded areas are protected against drying out, and in most forms of grafting rapid union is essential to maintenance of life in the scion.

Among the regrettable defects in horticultural terminology in some languages, including English, is the use of the term “grafting”

in two senses. Up to this point in the present discussion the term "grafted plant" has been used in its more inclusive application, signifying plants composed of united segments originally derived from two, or occasionally more, plants. The numerous operative procedures by which grafted plants are produced fall into two groups, known as budding and grafting. Though these terms are well understood in ordinary usage, definitive separation between them is impossible in some cases. Perhaps the best differentiation between budding and grafting is that offered by Baltet, who defines grafting as any method which employs as scion a portion of a plant comprising the complete circumference, however long the segment. This distinction considers only the mechanical operations involved with no reference to the manner in which union is established.

Union between stock and scion, always established through callus formation and subsequent differentiation may result from approximation of the cambium edges of stock and of scion in several ways. This is accomplished through union of a cambium edge with a cambium surface, in the so-called cleft and whip grafts, the bark graft, the bridge graft and some forms of approach graft. Or it may be brought about through placing the inner surface of the bark of the scion against the surface of the woody cylinder of the stock, as in "budding with wood removed." A very slight variation of techniques may change the manner of establishing unions; thus the experienced propagator may set one bud with "wood in" and the next with "wood out," resulting in a difference as to tissue union but not in the practical results. This statement of the manner in which unions are established explains why plants with cambium diffused only throughout the interior of the stem cannot be surface budded. In such plants chance might bring enough cambium into sufficiently close juxtaposition to establish union if splice grafting were employed.

Budding as generally understood is effected by raising or removing a segment of bark of the stock and inserting a segment of the scion, containing a bud, into the wound thus made. The piece inserted may be shield-shaped or a patch (fig. 1, B₁, B₂, B₃). In budding apple, pear, peach, orange, etc., the bark is lifted away from the wood around a T- or $\perp$ -shaped incision and the bud then inserted under the bark (fig. 1, C, D). After the bud is inserted simple tying generally affords ample protection against drying out. In budding nut trees better results are ordinarily obtained by removing a piece of bark, generally rectangular in shape, from the stock and fitting into the space from which it came a piece of bark carrying a bud, from the tree whose reproduction is desired. In these cases tying and waxing are generally employed. In all types of budding the ties should be tight enough to press the inserted portion firmly against the cambium covering the wood of the stock. It is obvious that ordinary budding is practicable only during the period in which the bark slips freely on the stock. Most budding in nurseries in temperate zones is done from midsummer to late summer. The shield of the inserted bud unites promptly with the stock but growth from the bud is not expected or desired until the following spring, when the stock is cut back close to the inserted bud to force its development. June budding is restricted in the U.S. chiefly to the peach and to the southern states. Seedlings growing from seed planted in the preceding spring are budded, actually in May rather than in June in many nurseries, the top of the stock broken over at once but not removed until the bud has made some growth. This procedure produces a budded tree ready for planting in the orchard in the autumn of the year in which the seed for the stock was sown.

Grafting is used, in one form or another, on plants either in the growing or in the dormant stage. Deciduous fruit trees are grafted ordinarily with dormant scions and frequently when the stocks are dormant. In many of them, *e.g.*, apple, callus formation is rather free at temperatures so low that bud opening is slow and some sort of union is established before visible growth begins. This permits bench grafting, a process in which dormant scions are grafted on small roots or pieces of roots, also dormant, during winter by workmen sitting at a bench. The grafted plants are stored in moist sand or sawdust until spring, when they are lined out in nursery rows. Dormant scions may be grafted into growing trees throughout the growing season but the growth of the scion and healing of

the stub consequent upon late grafting are much inferior to those obtained from spring grafting. In regions with rather mild winters, autumn grafting of deciduous fruits has sometimes succeeded; in this case union is apparently established before the advent of the lowest temperatures, but growth does not occur until spring.

Highly artificial treatments, either to hasten callus formation or to restrict loss of moisture, are requisite to success in grafting some plants. With grapes much higher proportions of successful grafts are obtained if the grafted dormant plants are subjected to temperatures around 80° F. for several days, while packed in boxes to

prevent loss of moisture. This process is generally so timed that when the sweating is completed the plants may be lined out in the nursery before the buds open. Some plants with evergreen foliage, as the orange, may be grafted by the use of scions from which the leaf blades have been removed, but grafted conifers are generally held in closed cases, somewhat shaded, to restrict moisture loss, until union between stock and scion is established. In many plants, including most conifers, root regeneration is so slow that they cannot be grafted successfully bare rooted, but the stocks must be well established in pots previous to the time of grafting. In grafting the mango, which is particularly difficult, small potted stocks are sometimes placed on stagings in close proximity to young shoots of the mother tree and the two are united by inarching or approach grafting, and the scion remains attached to the mother tree until it has united with the new stock. The litchi is frequently grafted in this manner.

The various types of operation by which stock and scion are so fitted together that they may unite by grafting number into the hundreds, but six of these will cover almost all requirements. The important considerations are obtaining ample surface of contact between the cambial zones of stock and scion and permitting ready healing of the wounded surfaces. As between methods which are satisfactory in these respects, choice depends principally on ease of execution and on the relative sizes of stock and scion. When the stock is much larger than the scion the cleft graft (fig. 2, A, B) or a bark graft (fig. 2, E) is more advantageous. The former, usable when the stock is dormant, *i.e.*, its bark does not slip, involves saw-

ing the stock at right angles to its stem, splitting the stem and then inserting scions with the bases cut approximately wedge-shaped so that their cambial zones (between bark and wood) lie alongside the similar zones of the stock. The bark graft (fig. 2, E) involves cutting off the stock as with the cleft graft, and either inserting a wedge-shaped scion between bark and wood of the stock or removing a portion of the bark into which is fitted exactly the scion from

FIG. 3.

Types of Inarching. Solon on left. Dotted line shows line of severance after union is established

which half the circumference of the basal portion has been removed. The bark graft is practicable only when the bark of the stock separates readily from the wood. Since these grafts are usually made above ground, all cut surfaces should be coated with grafting wax, or paraffin, to protect against drying out. These grafts can be made on stems of any size, but satisfactory healing is rarely obtained without undue effort when the stubs exceed two inches in diameter.

The splice graft and its modified form, the tongue graft (fig. 2, C, D), are suited to cases in which stock and scion are very nearly of the same size. A straight slanting cut, at a rather narrow angle, removes the top of the stock. A similar cut is made at the base of the scion. The two are so joined that the cambial zones match, and are tied securely in place. The tongue graft adds to the slanting cut a longitudinal split in the cut surfaces of stock and scion in each case about one-third of the distance from "toe" to "heel," and the fitting together of the tongues thus created. This tongue gives increased contact of cambium zones and the grafts are usually less easily displaced than in the simple splice. With stone fruits, however, the increased cutting seems to increase gum formation which is detrimental to the union and, in those stone fruits which are grafted, the simple splice seems preferable. Tongue grafts made by experts are often not tied; neophytes should tie them. Waxing is necessary when grafts are to stand above ground.

With conifers and with some other plants one of the side grafts is generally employed. Into the stem of the stock, generally rather close to the soil, a long diagonal downward cut, traversing about a third of the diameter, is made; into this is fitted the scion with its base trimmed to wedge shape. If the portion outside the knife as it makes the downward cut is removed and the scion, cut only on one side, is fitted against the exposed surface of the stock, the operation is known as veneer grafting. These two methods are suitable for use in cases where union of stock and scion are slow in accomplishment.

Inarching may be accomplished by making an upward diagonal incision in the scion and a similar downward incision in the stock, fitting together the two tongues thus created, tying in position and waxing (fig. 3, A). It may also be effected by removing a small longitudinal piece of bark and wood from the scion and fitting exactly the exposed portion of the scion into a slot on the stock from which the bark has been removed (fig. 3, B). Both of these methods permit union of stock and scion to be established before either is severed.

Bridge grafting is closely related to these in the structure of the approaches made, but its use is in tree repair rather than in propagation.

(F. C. Bd.)

PLANT QUARANTINE. Plant quarantine is that branch of law enforcement established by a country to prevent the introduction and distribution of foreign plant pests, principally insects and plant diseases, within its boundaries. The objective is to protect a nation's agriculture and horticulture from injury by any type of foreign plant pest that may be introduced. Similar regulatory procedures may also be adopted by a civil division within a country to prevent the internal spread of plant pests that have gained a limited foothold within its borders, or to facilitate eradication of such pests. Governmental agencies enforcing plant quar-

antine laws are variously designated in different countries as plant quarantine, plant protection, phytopathological and phytosanitary services. Most of these plant regulatory services are under the supervision of the national department or ministry of agriculture. The services usually operate in close co-operation with the customs service.

Plant Quarantine Service Operation.—Plant quarantine prohibitions and restrictions, applying to both the individual and the commercial shipper of such material, affect the importation of plants and plant products into most countries of the world. Plant quarantine regulations usually provide that before restricted plant material may be brought into the country the importer must apply in writing to the department of agriculture or equivalent agency for an import permit authorizing the entry of the desired items. Such a permit is also known as a certificate of introduction or import licence. This application allows the plant quarantine service to determine whether the consignment is prohibited entry, may enter under certain safeguards or is entitled to unrestricted entry. An import permit also informs the importer of any requirements for a phytosanitary or health certificate from the department of agriculture or some authorized official of the country of origin, certifying that the material has been officially inspected. Certification may also be required from the country of origin that the area where the material was grown is free of a particular pest, that the material was inspected in the field during the growing season or was grown beyond a certain distance from an area known to be infested by a specified pest, or that the material has been fumigated, disinfected or otherwise treated. The permit may also specify the port through which the material must be entered and the mode of transportation.

Upon arrival under the terms of the import permit, imported material, in general, is still subject to inspection by the plant quarantine service of the country of destination. If found infested or infected by injurious insects or plant diseases the material may require fumigation or other treatment. If such treatment is ineffective, the material may be destroyed or returned to the country of origin. Plant material for scientific purposes may enter under special provisions.

Examples of internal plant quarantine measures designed to control the spread of plant pests or to eradicate such pests are found in the rigid measures adopted by Great Britain to eradicate all infestations of the Colorado potato beetle (*q.v.*) and the interstate quarantines imposed by the U.S. to retard the spread of such pests as the Japanese beetle (*q.v.*), pink bollworm, white-fringed beetle and black stem rust of grains.

Insect Migration Between Countries.—The cosmopolitan nature of a country's insect population is illustrated by a statement of the U.S. department of agriculture in 1917 that "The majority of the insect pests of the United States which now occasion the greatest damage to orchard, field, and garden crops and to stored products and in homes, etc., are of foreign origin, and were introduced with the host plants or accidentally in the course of commerce." The statement was supported by a list of 110 of the most important insect pest introductions of previous years. Furthermore, the department listed about 1,800 insects which occurred in different parts of the world and were liable to be introduced at any time with nursery stock, in merchandise or as accidental stow-aways on ships or in baggage.

The rapid migration of a dangerous insect when allowed to spread freely through articles of commerce is well illustrated by the instance of the pink bollworm of cotton. (See COTTON and THE COTTON INDUSTRY: *Pests and Diseases of the Cotton Plant.*) This insect, a native of India, is the most destructive known pest of cotton. The worm exacts a double toll from the crop: it damages both the lint and the seed, resulting in loss of cotton and reduction in oil content of the seeds. About 1908 this pest was introduced into Egypt in bales of cotton from India. Destined for an Egyptian spinning mill, the ginned cotton contained a very high proportion of infested cottonseed. When the Egyptian infestation was discovered in 1910, the worm was already well established in widely separated localities.

In an attempt to get improved cotton varieties for planting in

the Laguna district of Coahuila, Mex., a cotton grower planted imported Egyptian cottonseed in a field near Monterrey, thereby introducing the pink bollworm to a new country. When this infestation was first reported in Nov. 1916, the worm was found to have spread throughout the entire Laguna district. Surveys were begun in the vicinity of 11 cottonseed-crushing mills in Texas that had received seed from the Laguna area. By the end of 1917, infestations had been found in cotton fields adjacent to two of the mills. Further, an extensive infestation was found late in 1917 at Anahuac, Tex., on Trinity bay. The latter spread was attributed to Mexican cottonseed that was washed far inland when the great storm of 1915 wrecked a Mexican steamship en route to Galveston, Tex. Thus in less than a decade a major cotton pest, through a series of intercontinental distributional leaps, was spread through commercial channels from Asia to Africa, and to the North American continent.

Horticultural items of exotic beauty may nevertheless serve as avenues for introducing noxious pests, as illustrated by the Japanese cherry trees around the Tidal basin in Washington, D.C. The first shipment of 2,000 trees received from Japan in 1910 was so heavily infested with insects that it was burned. While much freer of insect pests than the first gift shipment, a second lot of these trees imported from Japan and planted in 1912 was responsible for the introduction of the oriental fruit moth. Now spread throughout the U.S., this moth is one of the most destructive pests of peaches in that country.

Among the hundreds of noxious insects and plant diseases that countries seek to keep out are: the golden nematode of potatoes and tomatoes; pink bollworm of cotton and cotton boll weevil; harmful species of fruit flies, such as the Mediterranean, oriental and Mexican fruit flies and the melon fly; Colorado potato beetle; citrus canker; and various virus diseases.

Functions of a Plant Quarantine Service.—A comprehensive national plant quarantine service provides for the following:

1. Inspection stations at all important maritime, border and air ports of arrival to enforce all plant quarantine prohibitions and restrictions prescribed by the national government.
2. Inspection of surface ships and aircraft and their cargoes, stores and baggage, as well as arriving mail, express shipments and freight, at all ports of entry. In addition, at land ports of arrival, inspections are made of pedestrian, passenger-car and truck traffic, freight cars, passenger trains and dining cars. This inspection is for the purpose of determining whether arriving plant products meet the requirements for entry, or whether they must be treated, destroyed or re-exported.
3. Fumigation or other treatment of any type of carrier, cargo or products, or destruction of infested products or packing materials, when necessary to ensure freedom from injurious pests. The principal fumigants used by plant quarantine services are hydrocyanic acid gas, methyl bromide and ethylene dibromide. Release of an agricultural insecticidal aerosol in foreign aircraft may be required immediately upon landing.
4. Inspection of domestic plants and plant products intended for export and certification of the products to meet the phytosanitary requirements of the country of destination.

Air travel introduced an important additional hazard of pest spread. Insects particularly now have a much better chance of reaching another country alive, since the short elapsed time of air travel permits them to survive without food or water. For example, the oriental fruit fly was discovered in Hawaii in May 1946, presumably having travelled by military air transport from Saipan. In another instance, an overseas flight that originated in Cairo, Egypt, stopping en route at Paris, was found upon arrival in the U.S. on June 26, 1956, to contain 51 live adults of the European chafer (*q.v.*). The plant quarantine inspectors who searched the plane were informed by crew members that during their stopover in Paris the chafers were swarming "like bees" around the lights at the airport. The chafers were found in the passengers' compartment as well as in baggage and cargo compartments. This destructive insect already had been unwittingly introduced and established in several scattered areas of northwestern New York.

The benefits of a plant quarantine can be illustrated by California's experience in introducing the eucalyptus tree from Australia in the seed stage. This is the safest stage in which to make introductions, since clean seeds that have been surface treated and fumigated carry few insects or bacteria, fungus or virus organisms. In its native home the eucalyptus has a large number of insect enemies. Not a single Australian insect species was brought to California with the seeds. In contrast, eucalyptus importations, probably in the form of Australian-grown nursery stock, resulted in the introduction into South Africa and New Zealand of several destructive eucalyptus pests. By utilizing a perfectly natural plant quarantine barrier, California protected itself from pests that it might otherwise have received.

History of Plant Quarantine Development.—Prior to 1870 there was little realization by national governments of the dangers inherent in a free exchange of the plants and plant products that are hosts to injurious plant pests. As a result of this indifference, many harmful insects and destructive plant diseases travelled with their hosts to distant lands. In their new environments these pests frequently found hosts more susceptible to their attack. Natural enemies and other controls which often held them in check in their native home were absent. Characteristically, most introduced foreign pests become well established in a new country before their unwelcome presence is discovered.

Also, comparatively pest-free plants introduced into a new environment may be attacked by a previously unimportant pest. The pest may then spread throughout the range of the newly found host. Such was the case with the Colorado potato beetle, a relatively unimportant insect first described in 1824 and thriving on native weeds in the Rocky mountain area of the U.S. When cultivated Irish potatoes were planted nearby it fiercely attacked the new food crop and in the short span of 16 years, from 1859 to 1874, spread from Nebraska to the Atlantic coast of the U.S., an average annual migration of 85 mi.

Two North American insects that became established in European countries and in Australia were responsible for the inception of national plant quarantine legislation in the decade following 1870. During this decade, many national governments realized that destructive insects and disease-producing organisms are abundant in many parts of the world, ready to be taken to other countries and there attack the native agricultural and horticultural crops.

The Colorado potato beetle incidentally was responsible for the first legislation affecting the international movement of a plant product. This prolific pest was transported in potato exportations to Germany, where a localized infestation was found in 1874. Following eradication of the small infestation, a decree was issued by the German government on Feb. 26, 1875, forbidding the further importation of potatoes and potato sacks. This decree appears to be the pioneer in plant quarantine legislation affecting the international movement of a plant product. France also imposed exclusion measures against this new U.S. pest in 1875. These two exclusion orders antedated by only two years the Destructive Insect act adopted by the United Kingdom in 1877.

About 1859 the grape *Phylloxera* (see *PHYLLOXERA*), a native of eastern U.S., was introduced into France through the medium of imported grapevine cuttings. During the following 20 years the *Phylloxera* spread until it was established in the entire grape-growing area from Spain through central Europe to the Black sea district of Russia. Within 25 years after it was discovered in France it had destroyed nearly one-third of the French vineyards. Whereas the grape in *Phylloxera*'s native habitat had acquired practical immunity to its attack, European grape varieties proved easy prey. The sight of the small galls on the leaf and the gall-like swellings on the roots formed by this minute, aphidlike insect caused near panic among the growers when outbreaks grew to serious proportions. Similar shipments of vine cuttings from France to Australia about 1872 spread the *Phylloxera* to the latter country. Plant quarantine legislation to suppress this infestation was passed by the Australian legislature in 1877. This act gave power to quarantine and even to eradicate vines and destroy vineyards. In France regulation relating to *Phylloxera* was pro-

claimed in Oct. 1878.

The first widespread concerted action in Europe in the field of plant quarantine was taken in Nov. 1881, when an international conference held in Berne, Switz., drafted an international agreement known as the *Phylloxera* convention. The conference also considered means of preventing the introduction of the *Phylloxera* from the U.S. and restrictions and regulations on the movement of grapevines and grape products to prevent its further spread between European countries.

Adoption of the *Phylloxera* convention of 1881 emphasized to European nations the need for restrictions on the movement of plants and plant products to prevent the accidental introduction of alien insects and plant diseases. Within a few years plant quarantine restrictions affecting a number of U.S. plants and plant products in addition to the grape had been adopted by several European countries.

Most important of the emergent European plant quarantine orders was an embargo placed in 1898 on plant material that might be infested with the San Jose scale. This scale had been introduced into the United States from China with importations of such ornamentals as the flowering peaches that were planted on a large estate at San Jose, Calif., in 1870. The pest was named after the town where it was first observed. In 1880 the scale was recognized as the most pernicious pest of deciduous trees then known. Shipments of nursery stock from the San Jose area spread the scale to an orchard in Virginia and to several nurseries in Missouri, New Jersey and New York, where the infestations came to public notice in 1893. One state after another promulgated quarantines to keep out this pest. These quarantines were followed in a few years by practically world-wide quarantines banning the importation of U.S. plants and placing restrictions on the importation of U.S. apples and other fruits.

Legislation intended to control local infestations of the migratory grasshopper was enacted by the midwestern states of Kansas, Minnesota, Missouri and Nebraska in 1877. These laws made no attempt to control initial invasions by these pests, since this was considered impossible. The laws did provide for the compulsory destruction of migratory grasshoppers in localized areas already invaded. The object was prevention of further spread the following year through migratory flights from invaded areas.

In addition to its instigation of plant quarantine legislation among European nations, the grape *Phylloxera* was also the incentive for the first interstate plant quarantine in its country of origin. This pest was found in a vineyard near the town of Sonoma, Calif., in Aug. 1873. It had been accidentally transported from its native habitat in the eastern U.S. to California vineyards having European-type plantings. Sentiment for control legislation grew so strong among viticultural (vine-growing) and other horticultural interests that on March 4, 1881, the California legislature passed an act "to protect the interests of horticulture and viticulture," the first legislation adopted in the U.S. to prevent the spread of injurious insects. This act, as subsequently modified and strengthened, authorized state officials to require inspection and other measures to prevent the entry of pests from other states or from foreign countries. In 1890 California became, so far as is known, the first area in the world to inaugurate a system of maritime port inspection against insects and plant diseases. For 31 years following the act of 1881, California's was

the only existing legislation in the U.S. to protect the country from the entry of injurious foreign plant pests. The U.S. was the last of the major nations of the world to protect itself by law against the importation of plant pests. Its Plant Quarantine act was not passed until Aug. 20, 1912.

Professionally, plant quarantine is recognized by the Entomological Society of America through its section on control, extension and regulatory entomology and by the American Phytopathological society through its committee on regulatory work and foreign plant diseases. Courses in plant quarantine are offered in several colleges and universities in the U.S., including the universities of Florida (Gainesville) and Minnesota (Minneapolis) and Colorado Agricultural and Mechanical college (Fort Collins).

International Plant Quarantine Agreements.—Closer liaison between plant quarantine services of different countries was established as a result of the drafting of an International Plant Protection convention by the Food and Agriculture organization of the United Nations in 1951. This international agreement dealing specifically with plant quarantine matters became effective April 3, 1952. Its purpose is to strengthen co-operation among governments for the protection of plant resources. By May 1957, 38 governments, including signatories which had ratified it and subsequently adhering governments, had become parties to this convention which replaced the *Phylloxera* convention of 1881 and the International Convention for the Protection of Plants of 1929.

The 1951 convention provided, in part, for uniform phytosanitary certificates, the establishment of plant protection agencies by each contracting government, the promulgation of national quarantines only as biologically warranted, the creation of regional plant protection organizations, a world reporting agency and a procedure for settling international disputes.

By June 1957 regional plant protection organizations had been created in Europe, southeast Asia and the Pacific, and in Central America and Mexico. Similar regional organizations had been developed independently in that part of Africa south of the Sahara and in the southern half of South America.

A world-wide reporting service on plant diseases and pests was established by the Food and Agriculture organization in 1952 under the provisions of the International Plant Protection convention. The service issues a monthly publication, the *FAO Plant Protection Bulletin*, the first number of which appeared in Oct. 1952. Published in English, French and Spanish, the bulletin disseminates information on plant quarantine of world-wide interest, especially current reports on the occurrence, outbreak and control of insects and plant diseases of economic significance. The service also assembles information on all plant quarantine legislation and regulations in effect throughout the world. A *Digest of Plant Quarantine Regulations* was first published by FAO in 1949, prior to adoption of the convention. A more complete edition was issued in 1952, covering the regulations of 40 countries, and a supplement in 1954 covered 38 additional countries and territories.

BIBLIOGRAPHY.—Publications on the subject are somewhat fragmentary, being mostly scattered, brief references in textbooks, scientific papers and government bulletins. The background and plant disease phases of the subject are well covered in W. A. McCubbin, "The Plant Quarantine Problem," *Ann. Cryptog. Phytop.* (1954). See also H. S. Smith *et al.*, "The Efficacy and Economic Effects of Plant Quarantines in California," University of California College of Agriculture *Bulletin* 553 (Berkeley, Calif., 1933). (R. W. SH.)
